Abstract
With growing populations of patients in need of care and rapid increases in recent years in the availability and utilization of imaging, health systems around the world are turning more and more to radiology as a key component of the services they deliver. Coupled with growth in demand is stunning technological innovation in radiology. With radiologists now busy as ever and working on the cusp of one of the most exciting eras ever in the development of information technology, we must ask ourselves: Are we harnessing our capacity for innovation and technology development in the right ways? As health systems look to us increasingly for answers, what will our profession deliver to them? From PACS to advanced image processing to reduce radiation dose, information technology (IT) has been critical to the advance of radiology. Now we are experiencing new developments in IT, including clinical decision support, computer aided radiology and advanced systems for improved workflow and efficiency. Soon, resources we once thought of as "futuristic" will appear, including expanded artificial intelligence, sophisticated extraction of information (data mining) from the medical record and dramatic improvements in image quality and usage. Exciting new concepts in radiology, such as hyperpolarized carbon 13, steerable catheters and the use of intraluminal filters, will radically change the way we view our work. All the promise of medicine as practiced in “Star Trek” seems headed our way. The potential positive impact of all of this on patients is immense, but achieving it means embracing innovation in new ways, and working as a profession to ensure that technological change is managed effectively.

Abstract
Today’s political, economic, and health realities present significant opportunity to shape the United States health care system so it achieves the triple aim—providing better care for individuals and populations at reasonable cost. The U.S. health care system has entered a period of massive transformation, and national approaches to patient care, education, and research will need to adapt to the changing health care landscape. This plenary session will highlight the political and economic realities facing U.S. health care, including shifts away from fee-for-service toward population-based payments in health care financing, reductions in clinical revenue, stagnant research funding, and a demand for new approaches in medical education. In a time of enormous change in health care, physicians are challenged to provide sufficient leadership to manage changing practices. Unfortunately, many physicians today are embedded in a traditional culture of medicine—one that is hierarchical, autonomous, competitive, individualistic, and expert-centric. Evidence is beginning to demonstrate that this culture, which conflicts directly with the health care desires of patients in the 21st century, can have negative outcomes for patient care. Unless a major cultural shift can occur, this traditional approach will have serious repercussions for the future of health care. Successful transformation will require both innovation and a new kind of leader. This plenary session will highlight the critical success factors for health care leaders in this transformative
Clinical care in the 21st century requires new leaders who will foster a culture that is collaborative, team-based, service-based, mutually accountable, and patient-centered. Tomorrow’s physicians will need to adapt to—and even create—disruptive innovations in operating models, clinical care, education, and technology. Whether in independent group practice or as part of a large health system, radiologists, other health care providers, and their institutions will need to develop innovative and forward-thinking operating models for cost and quality performance to ensure long-term sustainability. Physicians of tomorrow must accept that they are stewards and leaders of this transformation.
PURPOSE
To evaluate the possibility of predicting local lymph node metastasis by extramural vascular invasion (EMVI) on preoperative MRI in patients with rectal cancer.

METHOD AND MATERIALS
MR images and clinical pathologic data of 183 consecutive patients with rectal cancer (between Dec. 2011 and Dec. 2014) were reviewed. MRI-detected extramural vascular invasion (mr-EMVI), with clinical pathologic factors (including age, gender, T stage, differentiation, size and pathological EMVI), were analyzed by chi-square crosstabs test (or t test) and multivariate logistic regression to determine risk factors for lymph node metastasis.

RESULTS
A total of 183 rectal cancer patients who underwent radical surgery were included in our study. Of them, 78 (42.6%) patients had lymph node metastasis according to pathology at the time of surgery. Among those clinical pathologic factors, T stage (odds ratio, 1.848), pathological EMVI (odds ratio, 4.878) and MRI-detected EMVI (odds ratio, 3.884) were independent risk factors for LNM. The incidence of LNM in the patients with pathological EMVI and MRI-detected EMVI was 78.7% and 75.4% respectively. By using pathological EMVI as a gold standard, sensitivity, specificity and agreement rate of MRI-detected EMVI were 61.7%, 82.3% and 77.0%.

CONCLUSION
MRI-detected EMVI could be used as a predictor for lymph node metastasis in patients with rectal cancer.

CLINICAL RELEVANCE/APPLICATION
This paper has shown that the lymph node status at the time of surgery in rectal cancer is related to preoperative MRI-detected extramural vascular invasion. The results may be useful for patients' selection for preoperative neoadjuvant therapy.

PURPOSE
One of the important aspects of rectal cancer staging is the measurement of the invasion depth of a tumour into the mesorectal fat in millimetres. This determines whether there is a T3ab (<5mm) or T3cd (>5mm), which changes treatment for patients (CRT yes/no). Measurement of this factor is arbitrary. Aim was to evaluate reproducibility of the measurement of invasion depth into the mesorectal fat by different readers.

METHOD AND MATERIALS
Sixty-one patients with a pathologically proven T3 tumour were selected. Two readers with different experience in reading rectal
SSA07-03  Interobserver Variability in Interpretation of High Resolution MRI of Primary Rectal Cancer

PURPOSE
To assess interobserver variability in the interpretation of high resolution MRI scans for staging primary rectal cancer

METHOD AND MATERIALS
MRI of 22 randomly selected cases with known rectal cancer, were evaluated independently by 4 abdominal radiologists with approximately 2-4 years of experience in reading rectal MRI. Criteria evaluated included T stage and depth of tumor invasion separately assessed as measured in mm and < or > 5 mm, lymph node involvement and vascular invasion. The data was tabulated and interobserver agreement was calculated. For the small percentage of patients who went directly to surgery correlation with final pathology was performed.

RESULTS
There was wide range in interobserver agreement between 2 readers in different sets/combinations, ranging from 68-90% with overall complete agreement among all readers in only 68% of cases with respect to depth of tumor invasion which improved to 82%, if depth of tumor invasion was separated in <5 mm versus > 5 mm. 5 patients had undergone surgery immediately after MRI without preoperative chemoradiation. In these cases, individual reader accuracy for pT1/T2 versus T3 staging was 60-100% with overall mean accuracy of 80% among all readers. Agreement between 2 readers in different combinations, ranged from 68-81% with overall complete agreement among all readers in 54% of cases with respect to presence or absence of vascular invasion. Interobserver agreement was noted in 76-90% cases and complete agreement among all readers in 68% cases with respect to lymph node status.

CONCLUSION
High resolution MRI is now a widely accepted modality in the preoperative staging of primary rectal cancer. Inter-observer variability remains a significant limitation.

CLINICAL RELEVANCE/APPLICATION
High resolution MRI is now widely used for triaging patients directly to surgery or chemoradiation followed by surgery. However there is significant variation in the interpretation of key parameters. This should be recognized to avoid overtreatment or undertreatment of patients.
RESULTS

291 patients with surgico-pathologically confirmed rectal adenocarcinoma, who had undergone preoperative MRI before any treatment, were retrospectively collected. Preoperative MRI features (tumor location and size, MRI-TN stage, status of circumferential resection margin (CRM), lymphovascular invasion (LVI)), clinical characteristics (age, gender, preoperative CEA value), operation information (operation method, tumor location) and pathologic outcomes (pTN stage, status of pCRM, pLVI, nerve invasion (pNI), number of regional metastatic lymph nodes (pMLN)), ratio of pMLN (pLNR), tumor grade) as well as immunohistochemical results were analyzed. Univariate and multivariate logistic regression models were performed to predict the risks of distant metastasis. The Kaplan-Meier method was used to analyze the disease-free survival (DFS) rate and 3-year overall survival (OS) rate.

RESULTS

Among 291 patients, 69 patients (23.7%) were confirmed to have distant metastasis. In univariate analysis, MRI-T stage (P<0.005), MRI-N stage (P<0.001), CEA value (P=0.007), pT stage (P<0.001), pN stage (P<0.001), pMLNs (P<0.001), pLNR (P<0.001), tumor deposits (P=0.014), pLVI (P=0.005), pNI (P=0.003) correlated significantly with synchronous distant metastasis. In multivariate analysis, only preoperative CEA values (P=0.038, Exp (B)=2.102), pLNR (P<0.001, Exp (B)=23.780) and pT stage (P=0.005, Exp (B)=3.677) were independent risk factors for distant metastasis. The mean DFS period for both groups was significantly different (57.2±40.62 vs 18.88±4.98 months, P<0.001). The 3-year OS rate for patients with distant metastasis was 35.0% compared with 97.1% for those without distant metastasis (P<0.001).

CONCLUSION

Preoperative MRI provided limited value in prediction of metachronous distant metastasis in patients with rectal cancer as independent risk factor. Comparing with MRI features, preoperative CEA values, pLNR, and pT stage were independent risk factors. Patients with the risk factors should be closely followed up for monitoring the metachronous metastasis status in order to take measures for the hope of a good survival outcome.

CLINICAL RELEVANCE/APPLICATION

Compared with MRI features, CEA values, pLNR and pT stage were independent risk factors to predict metachronous distant metastasis in patients with rectal cancer.

SSA07-05 MRI Detected Tumor Response for Intermediate Stage Rectal Cancer(RC) Treated with Chemotherapy Predicts Disease Free Survival and Recurrence: A Collaborative Group Experience

PURPOSE

Intermediate risk* RC patients may benefit from neoadjuvant chemotherapy as staging MRI shows markers for distant disease but clear potential resection margins making local recurrence unlikely. This exhibit assesses MRI and pathological staging following neoadjuvant chemotherapy for intermediate risk RC in a prospectively enrolled multicenter phase II trial.

METHOD AND MATERIALS

The trial evaluated safety and efficacy of neoadjuvant Capecitabine, Oxiplatin and Bevacizumb(CAPOX-B). Forty-six patients were enrolled between 2009-11. Eligibility included baseline magnetic resonance (MR) showing a T3 tumour with mesorectal fascia (MRF) potentially clear. Baseline Nodal and Extra-mural venous invasion (EMVI) status was also recorded. Response was assessed by post-treatment MR and pathological T, N and EMVI status as well as Tumor regression grade (TRG). Additionally MR tumor length change, mrEMVI reversion and pathological T downstaging were recorded. Three-year disease free survival and recurrence were calculated using Kaplan-Meier. Cox proportional regression determined relationships between outcomes and all recorded imaging and pathology variables divided into good and poor responders. Three separate Cox-regression analyses were also performed for: baseline imaging, post-treatment imaging and pathology variables.

RESULTS

Forty-six patients were...
Median follow-up was 36 months, fourteen patients experienced relapse. 3-year DFS was 69%. On Cox multivariate analysis including all factors mrEMVI(p=0.028) and T-downstaging(p=0.032) were independent prognostic factors for DFS. mrEMVI(p=0.040), T-downstaging(p=0.013) and ypN(p=0.041) were significant independent factors for recurrence. Significant univariate factors for DFS were: Baseline mrEMVI status(p<0.001), mrEMVI reversion(p=0.003), post-treatment MR T staging(ymrT)(p=0.007), mrTRG(p=0.011), pathological nodal status(p=0.02) and T-downstaging(p=0.0009). Significant univariate factors for recurrence were: mrEMVI(p=0.007), ymrT (p=0.008), mrTRG(p=0.019), T-downstaging(p=<0.0001), ypN(p=0.002) and ypT(p=0.022).

CONCLUSION
Baseline MRI-EMVI is an independent prognostic factor for survival and recurrence in intermediate risk rectal cancer treated with neoadjuvant chemotherapy.

CLINICAL RELEVANCE/APPLICATION
Future randomised trials should evaluate primary chemotherapy versus standard treatment in patients with T3,MRF clear and mrEMVI positive disease. Moreover mrEMVI positive may be recommended as a stratification factor.

SSA07-07 Imaging Genomics of Colorectal Cancer: Patterns of Metastatic Disease at Time of Presentation Based on Mutational Status

Sunday, Nov. 29 11:45AM - 11:55AM Location: E450A

Participants
Cynthia Cruz, MD, Boston, MA (Presenter) Nothing to Disclose
James H. Thrall, MD, Boston, MA (Abstract Co-Author) Board Member, Mobile Aspects, Inc; Board Member, WorldCare International Inc; Consultant, WorldCare International Inc; Shareholder, Antares Pharma, Inc; Shareholder, iBio, Inc; Shareholder, Peregrine Pharmaceuticals, Inc
Debra A. Gervais, MD, Chestnut Hill, MA (Abstract Co-Author) Nothing to Disclose

PURPOSE
To identify the most frequent genetic traits associated with metastatic colorectal tumors at time of presentation and whether there is a correlation between the genotypes and the metastatic disease patterns.

METHOD AND MATERIALS
Retrospective review of 713 subjects with cross-sectional imaging at time of diagnosis with no previous treatment. All tumor samples were tested for Single Nucleotide Polymorphisms (SNP). Mutations can be present individually or coexisting. Z tests were...
Three-hundred-ninety-seven males and 316 females. Metastatic disease in 547/713 (76), 385/487(79) mutants (M) and 162/226(72) wild types (WT) (p=0.02). Incidence of metastatic disease per genotype as follows: NRAS 31/35(89%), KRAS 213/244 (87%), APC 47/55(85%), TP53 142/170(84%), PIK3C 9/81 (73%), BRF 56/7/1(71%) and WT (72%)162/226. Metastasis to the liver, lymphnodes (LN), peritoneum and lung were observed with all genotypes. Liver:LN proportion of involvement was seen as follows: KRAS 62:28 (p<0.001), BRAF 55:62, NRAS 71:58, TP53 63:59, PIK3C 69:49, APC 64:47 and WT 51:49. Metastatic site involvement exclusive to certain genotypes was observed: duodenum/ Kidneys/ Uterus/ Cervix/ Vagina: KRAS+TP53, Brain:TP53, Appendix: KRAS, Retroperitoneum:PIK3C/WT and Bladder/ Pancreas/ Prostate/ Mediastinum: WT. All genotypes except for BRAF demonstrated bone metastasis.

CONCLUSION
Our study suggests there is an association between mutational status and patterns of metastatic disease in Colorectal Cancer. Metastatic disease to the bladder, pancreas, prostate and mediastinum in CRC suggests wild type tumors. A lower involvement of LN suggests the presence of KRAS mutation.

CLINICAL RELEVANCE/APPLICATION
Genetic profiling should guide the search for specific metastatic patterns allowing special consideration for unusual sites of involvement of metastatic disease to suggest the presence of a specific mutation.

Debra A. Gervais, MD - 2012 Honored Educator

PURPOSE
We investigated the potential use of dynamic contrast-enhanced MRI (DCE-MRI) to discriminate responders from non-responders after neoadjuvant chemo-radiotherapy (CRT) in locally-advanced rectal cancer (LARC) affected patients. To this aim, a novel quantitative index, the Standardized Index of Shape value (SIS) and a consolidated one, the [18F]2-fluoro-2-deoxy-D-glucose positron emission tomography (FDG PET) via FDG Standardized Uptake Value (SUV), were compared.

METHOD AND MATERIALS
100 consecutive patients with LARC were enrolled in a prospective study approved by our Ethical Committee. A written informed consent was obtained for each patient. After surgery, the pathological TNM and the tumor regression grade (TRG) were estimated. DCE-MRI quantitative analysis was performed by measuring SIS value. Reduction of FDG SUV was also calculated for each patient. 75 patients were included in the statistical analysis because 25/100 patients did not perform MRI and/or FDG PET according to the predefined schedule. Non-parametric sample tests, receiver operating characteristic analysis and diagnostic performance were assessed.

RESULTS
Fifty-five patients (73.3%) were identified as responders, while 20 (26.7%) were considered non-responders. Assessment via SIS reached a sensitivity of 93%, a specificity of 80% and an accuracy of 89%, whilst SUV reached a sensitivity of 67%, a specificity of 75% and an accuracy of 70%.

CONCLUSION
In order to better to discriminate responder by non responder and predict neo-adjuvant therapy response in LARC, SIS obtained more interesting results when compared with SUV, increasing the sensitivity and negative predictive values, respectively with a gain of 26% and 34%.

CLINICAL RELEVANCE/APPLICATION
SIS percentage change could play a relevant role in LARC management improving the ability to identify complete pathological response, thus allowing for conservative strategy or for a "wait and see" policy, reducing significant morbidity and functional complications related to a total mesorectal excision (TME).
**PURPOSE**

To evaluate the association of texture of locally advanced rectal cancer in computed tomography (CT) with neoadjuvant concurrent chemoradiotherapy treatment (CRT) response and 3-year disease-free survival (DFS).

**METHOD AND MATERIALS**

Institutional review board approved this retrospective study and waived the requirement of informed patient consent. 95 consecutive patients who had neoadjuvant CRT followed by surgery for locally advanced rectal cancer have been included. Texture features were assessed with pretreatment CT scans by using independently developed software. Entropy, uniformity, kurtosis, skewness, and standard deviation were obtained from the largest axial image of the tumor (its boundary being manually drawn), without filtration and with Laplacian of Gaussian spatial filter of various filter values for fine (1.0), medium (1.5 and 2.0), and coarse (2.5) textures. Dworak pathologic grading was used for treatment response. Mean value of each texture parameter was compared between treatment responder (grade 3 and 4) and non-responder (grades 1 and 2) groups via independent t-test. Kaplan-Meier analysis was used to find the relationship between CT texture and 3-year DFS. Receiver operating characteristic curve was performed to determine the optimal threshold values. Using Cox proportional hazards model, independence of texture parameters from patient's stage and age was assessed.

**RESULTS**

Treatment responder group (n = 32) showed fine-texture features (lower entropy, higher uniformity, and lower standard deviation) with statistical significance in no filtration, and fine (1.0) and medium (1.5) filter values. Without filtration, Kaplan-Meier survival plots for entropy, uniformity, and standard deviation were significantly different (P = .03, P = .016, and P = .033) and fine-texture features (≤ 6.7 for entropy, > 0.0100 for uniformity, and ≤ 28.06 for standard deviation) were associated with higher 3-year DFS. Entropy, uniformity, and standard deviation were independent factors from the cancer stage and age in 3-year DFS (P = .033, P = .011, and P = .04).

**CONCLUSION**

Fine-texture features are associated with better neoadjuvant CRT response and higher 3-year DFS in patients with locally advanced rectal cancer.

**CLINICAL RELEVANCE/APPLICATION**

Our study implies the possibility of texture analysis as an imaging biomarker for the treatment response of neoadjuvant CRT and 3-year DFS in locally advanced rectal cancer.
**SSA08**

**ISPS: Gastrointestinal (HCC)**

**SSA08-02** Performances of Imaging for the Diagnosis of Small HCC Following the Recommendations of the European and American Association for the Study of the Liver

Participants
Shahid M. Hussain, MD, PhD, Omaha, NE (Presenter) Nothing to Disclose

**PURPOSE**

To evaluate, in a large population of patients with chronic liver disease, the performances of the different imaging techniques (contrast enhanced ultrasound (CEUS), CT scanner and MRI) alone and in combinations for the characterisation of hepatic nodules smaller than 3cm. This study was supported by a national institutional grant (PHRC 2008)

**METHOD AND MATERIALS**

From April 2010 to April 2013, 442 patients with a chronic liver disease have been prospectively included in 16 centres. They had 1 to 3 nodules 10 to 30 mm explored by CEUS, CT scanner and a MRI within a month. The examination was regarded as positive if the nodule displayed the typical landmark of HCC as defined by the European and American Association for the Study of the Liver (EASL and AASLD) recommendations. A composite gold standard was constructed with histology, imaging and follow up. We determined sensitivity and specificity for a given exam alone and for various combinations of exams as single tests. Results were given regarding the size of the nodules: 10-20mm and 20-30 mm.

**RESULTS**

382/442 patients with 551 nodules have been finally kept for the statistical analysis. They were 315 (82.46%) males; the mean age was 62.06 +/- 9.73 years. The causes of the chronic liver disease were mainly alcohol (58.12%), C virus (31.41%) and metabolic syndrome (19.11%). The mean size of the nodules was 18.15 +/- 5.74mm. For the 10 - 20mm nodules (n=347) sensibility for the diagnosis of HCC was 70.2% for MR, 67.6% for CT scanner and 39.9% for the CEUS; and the specificity was respectively 83.1%, 76.6% and 93.5%. For the 20 - 30mm nodules (n=204) sensibility for the diagnosis of HCC was 70.5% for MR, 67.5% for CT scanner and 52.4% for the CEUS; and the specificity was respectively 97.3%, 97.3% and 100%.For the 10 - 20mm nodules the sensibility and specificity were respectively 54.8% and 100% for the association of CT + MR; 27.7% and 100% for CT + CEUS; and 28.7% and 99.4% for MR and CEUS.

**CONCLUSION**

This study validates the use of sequential application of CT and MRI as recommended in the recent update of EASL and AASLD guidelines, in case of small HCC and in a large population. It shows the potential interest of CEUS for its high specificity. This study is part of the CHIC group.

**CLINICAL RELEVANCE/APPLICATION**

Recent updates of EASL and AASLD recommendations for the non invasive diagnosis of HCC are validated for the small HCC in a large population.
Preoperative MRI staging system may be comparable to the postoperative AJCC staging system in predicting prognosis following curative resection of hepatocellular carcinoma (HCC). To compare the diagnostic accuracy of different staging systems, we reviewed the medical records of 2,210 patients who had undergone biopsy, resection, or explantation of liver from January 2011 to November 2013 in our institution. Ninety three patients (M:F=69:24; mean age: 54.8, range 30-77) with chronic hepatitis B and/or cirrhosis for any etiology who had focal hepatic lesions ≥ 5 mm reported on dynamic contrast enhanced CT or MR were included. The focal hepatic lesions treated prior to imaging were excluded. A total of 144 lesions were finally included in our study with 73 lesions ≥ 2 cm, 55 lesions between 1-2 cm, and 16 lesions < 1 cm. The focal hepatic lesions were retrospectively evaluated on dynamic contrast CT or MR by use of different noninvasive diagnostic criteria of HCC including LI-RADS (2014), OPTN-UNOS, AASLD, NCCN, EASL-EORTC, and KLCSG-NCC. Using the pathology reports as a gold standard, sensitivity, specificity, and accuracy of the diagnostic criteria were analyzed.

RESULTS

The sensitivity was highest and equal with AASLD, NCCN, EASL-EORTC and KLCSG-NCC criteria (84.4%), followed by LI-RADS (77.9%) and OPTN-UNOS criteria (75.3%). The specificity was highest with OPTN-UNOS criteria (92.5%), followed by LI-RADS (90.0%), AASLD, NCCN, EASL-EORTC and KLCSG-NCC (82.1%). The accuracies were 83.3%, equal for all noninvasive diagnostic criteria.

CONCLUSION

AASLD, NCCN, EASL-EORTC and KLCSG-NCC had the highest sensitivity whereas OPTN-UNOS had the highest specificity among all six guidelines. LI-RADS could not provide higher specificity than OPTN-UNOS criteria or high sensitivity than AASLD or EASL criteria.

CLINICAL RELEVANCE/APPLICATION

Though LI-RADS 2014 is widely used by radiologists, it provides lower specificity than OPTN-UNOS criteria as well as lower sensitivity than AASLD or EASL criteria for noninvasive diagnosis of HCC.
curative resection of HCC. Furthermore, tumor stage 2 of the MRI staging system may be further divided into T2a and T2b.

**CLINICAL RELEVANCE/APPLICATION**

These advantages (preoperative staging and further stratification of T2 into T2a/b) can make the devised MRI staging useful in deciding on treatment plans of patients with HCC.

**SSA08-05  Utilising the Full Potential of MRI in the Diagnosis of HCC - Time for a Game Changer?**

**Sunday, Nov. 29 11:25AM - 11:35AM Location: E450B**

**Participants**

Kelvin Cortis, MD, FRCR, Msida, Malta (Presenter) Nothing to Disclose

Rosa Liotta, Palermo, Italy (Abstract Co-Author) Nothing to Disclose

Roberto Miraglia, MD, Palermo, Italy (Abstract Co-Author) Nothing to Disclose

Fabio Tuzzolino, Palermo, Italy (Abstract Co-Author) Nothing to Disclose

Angelo Luca, MD, Palermo, Italy (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

The current cornerstone of HCC diagnosis is the wash-in/wash-out enhancement pattern. It is known that HCC might exhibit other MRI findings. Our aim was to retrospectively review the MRIs of histologically proven HCCs on liver explants, and to identify the best combination of sequences useful in HCC diagnosis.

**METHOD AND MATERIALS**

97 consecutive patients who underwent liver transplantation between 2004 and 2012 and Gd-BOPTA-MRI within 3 months of surgery were enrolled. A hepatobiliary histopathologist and two radiologists blinded to the radiological/histopathological findings performed a nodule by nodule analysis. The signal intensity of all nodules was assessed on the following axial sequences: T1 in/opposed phase, 3D fat suppressed (FS) T1 (pre-contrast, arterial, portal, equilibrium, and hepatobiliary phases), T2, T2 FS, and diffusion (B=800). Arterial enhancement was graded as none, mild, moderate, or intense. A multiple logistic regression analysis was performed following pathological/radiological correlation, and the Odds Ratio (OR) was calculated for every parameter analysed and adjusted for nodule size.

**RESULTS**

Imaging was performed 41.7±25.4 days pre-transplantation. 291 lesions were identified on histopathology, of which 193 were HCCs, 68 regenerative nodules, 8 low-grade dysplastic nodules (DN), 19 high-grade DN, 2 cholangiocarcinomas, and 1 necrotic nodule. 48 HCCs (24.9%) were not detectable on imaging (24.9%), leaving a total of 145 HCCs (≤ 10 mm n=25; 11-19 mm n=58; ≥ 20 mm n=62). As expected, intense (OR 10.9, p<0.000) or moderate (OR 2.2, p=0.003) arterial enhancement and hypointensity on the portal venous (OR 14.3, p<0.000) or equilibrium (OR 15.9, p<0.000) phases were found to predict HCC. In addition, nodules showing hypointensity on the hepatobiliary phase and T2 hyperintensity were also highly likely to represent HCC. In the former, an OR of 10.2 was observed (p<0.000). The OR was 14.3 in non-FS T2 weighted sequences, and 10.2 in FS T2 weighted sequences (p<0.000).

**CONCLUSION**

In patients with a high risk of HCC, nodules lacking the typical hemodynamic findings are most likely HCC if they exhibit T2 hyperintensity and/or hypointensity on the hepatobiliary phase with an OR of 14.3 and 10.2, respectively (p<0.000).

**CLINICAL RELEVANCE/APPLICATION**

MRIs targeted at diagnosing HCC should include T2 weighted sequences with and without FS and Gd-BOPTA/Gd-EOB-enhanced hepatobiliary phases alongside standard sequences.

**SSA08-06  A Tumor Suppression Factor HNF4a (Hepatocyte Nuclear Factor) Expression Correlates with Gadoxetic Acid Enhanced MRI Findings in Hepatocellular Carcinoma**

**PURPOSE**

Hepatocyte nuclear factor (HNF) 4A is one of transcription factors with tumor suppression effect, and besides, regulates expression of many molecules including organic anion transporting polypeptide (OATP) 1B3 (uptake transporter of gadoxetic acid) in hepatocellular carcinoma (HCC) (Yamashita T, Hepatology 2014). The purpose of this study is to clarify the correlation between HNF4A expression, pathological findings and imaging findings on gadoxetic acid enhanced MRI.

**METHOD AND MATERIALS**

The subjects are 138 surgically resected HCCs. We semiquantitatively evaluated the immunohistochemical HNF4A and OATP1B3 expression of HCC into four grades: grade 0: no expression, grade 1: weak expression, grade 2: moderate expression and grade 3:
intensive expression. We compared HNF4A grade of HCCs with OATP1B3 grade, enhancement ratio on the hepatobiliary phase of gadoxetic acid enhanced MRI and histological tumor differentiation grade (well, moderately and poorly differentiated HCC).

RESULTS

HNF4A grade in HCC showed a significant positive correlation with OATP1B3 grade (P=0.003, r=0.46). There was also a significant positive correlation between HNF4A grade and enhancement ratio on the hepatobiliary phase of gadoxetic acid enhanced MRI (P<0.0001, r=0.49). Especially, intensive HNF4A expression was observed in atypical HCC showing high enhancement ratio and increased OATP1B3 expression. HNF4A grade was decreased according to the decline of differentiation grade of HCC (P=0.0007, r=0.29).

CONCLUSION

The expression of HNF4A in HCC correlated with both of OATP1B3 expression and enhancement ratio on the hepatobiliary phase of gadoxetic acid enhanced MRI. In addition, HNF4A expression was decreased during multistep hepatocarcinogenesis. Gadoxetic acid enhanced MRI is useful to evaluate the expression of HNF4A in HCC.

CLINICAL RELEVANCE/APPLICATION

Gadoxetic acid enhanced MRI has a potential to reflect the expression of many genes and molecules regulated by HNF4A as imaging biomarkers (radiogenomics), which will be important for future personalized medicine.

SSA08-07 Presence of Hypovascular and Hypointense Nodules on Preoperative Gadoxetic Acid-enhanced MR Imaging: An Important Risk Factor for Recurrence after Liver Resection for Hypervascular Hepatocellular Carcinoma

Sunday, Nov. 29 11:45AM - 11:55AM Location: E450B

PURPOSE

The hepatocyte phase (HP) of gadoxetic acid-enhanced magnetic resonance imaging (EOB-MRI) can reveal numerous hypovascular and hypointense nodules with malignant potential, which may progress to conventional hypervascular hepatocellular carcinoma (HCC). We retrospectively evaluated the prognostic factors for patients with hypervascular HCC after liver resection, including the presence of hypovascular hypointense nodules on HP of EOB-MRI (hypo-nodule).

METHOD AND MATERIALS

In total, 114 consecutive patients who had undergone surgical resection and were pathologically diagnosed with moderately differentiated HCC were included. For the analysis of risk factors for recurrence and a poor survival rate after liver resection, univariate and multivariate Cox regression analyses were performed for the following factors: age, tumor size, tumor number, vascular invasion, TNM stage, albumin level, prothrombin ratio, Child-Pugh class, alpha-fetoprotein level, protein induced by vitamin K absence/antagonist-II (PIVKA-II), liver cirrhosis, past history of HCC, and presence of hypo-nodules on HP of gadoxetic acid enhanced MRI. We compared the 5-year recurrence-free and overall survival rates between patients with and without hypo-nodules on HP of EOB-MRI.

RESULTS

Univariate and multivariate analyses revealed the presence of hypo-nodules as the only significant risk factor for recurrence after liver resection (risk ratio, 2.1 and 2.1; p-value, 0.014 and 0.020) and albumin level as the only significant risk factor for a poor survival rate (risk ratio, 10.3 and 6.1; p-value, <0.001 and 0.019). The 5-year recurrence-free rate was significantly lower for patients with hypo-nodules (13.1%) than for those without (48.8%; p = 0.008); similar results were observed for the 5-year survival rate (66.1% vs. 83.4%), although the difference was not significant (p = 0.222).

CONCLUSION

The presence of hypo-nodules on HP of preoperative EOB-MRI is an important risk factor for recurrence after liver resection for hypervascular hepatocellular carcinoma.

CLINICAL RELEVANCE/APPLICATION

The presence of hypovascular and hypointense nodules on hepatocyte phase of preoperative gadoxetic acid-enhanced MR imaging is an important risk factor for recurrence after liver resection for hypervascular hepatocellular carcinoma.

SSA08-08 Hepatocellular Carcinoma without Gadoxetic Acid Uptake on Preoperative MR Imaging: An Important Prognostic Risk Factor after Liver Resection

Sunday, Nov. 29 11:55AM - 12:05PM Location: E450B

PURPOSE

Hepatocellular carcinomas (HCCs) commonly demonstrate hypointensity compared with the surrounding liver parenchyma on the hepatocyte phase (HP) of gadoxetic acid-enhanced MR imaging (EOB-MRI). However, some hypervascular HCCs with gadoxetic acid (EOB) uptake demonstrate iso- or hyperintensity on HP. Such lesions are known to be biologically less aggressive. A previous study showed a lower recurrence rate for hyperintense HCC than for hypointense HCC. In this study, we retrospectively evaluated the overall survival rate for patients with hyperintense and hypointense HCC on EOB-MRI.

METHOD AND MATERIALS

In total, 114 consecutive patients with moderately differentiated HCC that was surgically resected from January 2008 to December 2013 were included in this study. According to their signal intensity on HP of EOB-MRI, the 114 patients were classified as EOB uptake (+) HCC (n = 23) and EOB uptake (-) HCC (n = 91). Risk factors for recurrence and a poor survival rate after liver resection were analyzed by univariate and multivariate Cox regression analyses of the following factors: age, tumor size, tumor number, vascular invasion, TNM stage, albumin level, prothrombin ratio, Child-Pugh class, alpha-fetoprotein level, protein induced by vitamin K absence/antagonist-II (PIVK-A-II), liver cirrhosis, past history of HCC, and EOB uptake on HP of preoperative EOB-MRI. Then, we calculated the overall survival and recurrence-free rates for both groups using Kaplan-Meier survival curves. The log-rank and Wilcoxon tests were used to analyze significant differences.

RESULTS

The absence of EOB uptake was found to be a significant risk factor for a poor survival rate after liver resection (risk ratio, 5.4; p < 0.05). The EOB uptake (+) group showed a higher overall survival rate compared with the EOB uptake (-) group (5-year survival rate, 100% and 73.3%; p < 0.05). However, the recurrence-free rate was not significantly different (p = 0.70).

CONCLUSION

The absence of EOB uptake was a significant risk factor for a poor survival rate after liver resection. The overall survival rate was higher for patients with EOB uptake than for those without.

CLINICAL RELEVANCE/APPLICATION

In patients with moderately-differentiated hepatocellular carcinoma, the absence of gadoxetic acid uptake is a significant risk factor for a poor survival rate after liver resection. The overall survival rate is higher for patients with gadoxetic acid uptake than for those without.
hepatocellular carcinoma microvascular invasion.
The Role of Peak Enhancement Values in Differentiating Pheochromocytomas from Adrenal Adenomas on CT

PURPOSE
The purpose of this study is to establish the role of the peak enhancement Hounsfield Unit (HU) value of focal adrenal lesions in differentiating potential pheochromocytomas from adrenal adenomas.

METHOD AND MATERIALS
The peak enhancement HU values of histologically confirmed pheochromocytomas (n = 24) were retrospectively compared with those of histologically confirmed adrenal adenomas (n = 28) on the 60-second contrast enhanced venous phase and compared utilizing a chi-square test. The studies were performed over a period of 5 years (2009-2014) on multi-detector CT scanners (MDCT). HU values were also measured on unenhanced (n = 34) and 15-minute delayed contrast enhanced (n = 27) phases. Measurements were obtained by drawing a representative region of interest over the target lesion. Peak enhancement values were recorded and absolute washout, relative washout and absolute enhancement (60-second enhanced minus unenhanced) were also calculated when available. Mass size was also recorded. The Student t test was used for comparing absolute enhancement and mass size.

RESULTS
83.3% (n = 20) of pheochromocytomas demonstrated a peak enhancement value of 85 HU or greater, compared to 10.7% (n = 3) of adrenal adenomas (p < 0.001, PPV = 86.96%, NPV = 86.2%). Absolute enhancement of pheochromocytomas was also higher than that of adrenal adenomas (mean = 66.2 HU [range, 51-95 HU] vs. 48.1 HU [range, 18-74]; p < 0.005). Of the pheochromocytomas imaged with a triphasic protocol (n = 9), 77.8% (n = 7) met absolute and relative washout criteria for the diagnosis of a lipid-poor adenoma (>= 60% and >=40% respectively). Pheochromocytomas were significantly larger than adrenal adenomas (mean diameter, 4.5 cm [range, 1-8.3 cm] vs. 1 cm [range, 0.8-6.2 cm]; p < 0.0001).

CONCLUSION
Peak enhancement values of 85 HU or greater in an adrenal lesion on the 60-second post contrast phase strongly suggest a diagnosis of pheochromocytoma rather than adrenal adenoma, regardless of whether or not the lesion demonstrates absolute or relative washout characteristics compatible with a lipid poor adenoma.

CLINICAL RELEVANCE/APPLICATION
Peak enhancement values on the 60-second post contrast phase should be routinely assessed in the workup of an adrenal lesion to avoid missing a pheochromocytoma.
Cerebral Cavernous Malformation Type I (CCM1) is an autosomal dominant disorder characterized by multiple cavernous malformations in the brain that may cause seizures, cerebral hemorrhage, or focal neurologic deficits. Abdominal manifestations are unproven and poorly described. Individuals of Hispanic descent in the Southwestern US are disproportionately affected by this condition due to a founder mutation in the CCM1/KRIT1 gene. Our aim was to investigate whether adrenal calcifications on CT are associated with CCM1 in carriers of the common Hispanic mutation (CHM).

METHOD AND MATERIALS
In an IRB-approved, HIPAA-compliant study, abdomen CT scans of 23 CCM1 subjects (10 F, 13 M, mean 51 yrs, range 24-73 yrs) were retrospectively reviewed. All subjects had multiple CCM lesions on brain MRI; 11 had confirmed CHM genotype. As controls, abdomen CTs from 38 unaffected matched subjects (18 F, 20 M, mean 48 yrs, range 23-73 years) and 13 subjects with sporadic (non-familial) CCM (6 F, 7 M, mean 51 yrs, range 26-72 yrs) were reviewed. Size, location, number, laterality of calcifications, and adrenal morphology were recorded. Brain lesion count was recorded for CCM1 subjects. Statistical comparisons between groups were calculated using Fisher exact test and two-sample t test.

RESULTS

15 of 23 CCM1 subjects (65%) had small (≤ 5mm), focal calcifications (SFC) in one or both adrenals, compared with 0 in unaffected and sporadic CCM subjects (p<0.001). SFC were either left-sided or bilateral. Glands with SFC had normal adrenal morphology. The presence of SFC correlated positively with number of CCM brain lesions (p=0.048); bilateral SFC correlated positively with patient age (p=0.030).

CONCLUSION

SFC are found in a majority (65%) of adults with CHM-related CCM1 and may be a clinically silent disease manifestation. SFC in this population are predominantly left-sided, more often bilateral with increasing age, and more common in patients with greater number of brain lesions. These findings add to existing evidence that CCM1 is a multi-system disorder with effects beyond the central nervous system. CCM1 should be considered in the differential diagnosis for focal adrenal calcifications encountered incidentally on CT.

CLINICAL RELEVANCE/APPLICATION

Incidental adrenal calcifications on CT may detect unrecognized CCM1 and improve diagnostic confidence in equivocal cases. Recognition of this entity is important for management of neurologic manifestations and genetic counseling.
The clinical manifestations and CT images for 30 patients with 31 lesions confirmed by pathological results from surgery were reviewed retrospectively. All of the patients were examined by a pre-contrast scan (true non contrast; TNC) and then arterial and venous phase enhanced scan. Then enhanced examinations were performed with dual-energy scan mode (SOMATOM Flash, Siemens Healthcare, Forchheim, Germany). The dedicated post processing application Liver VNC was used to get VNC images at the arterial and venous phase respectively. Mean CT values, signal-to-noise ratio, subjective image quality, and radiation dose were compared between routine TNC and VNC. The correlation between TNC and VNC images of the adrenal adenoma was evaluated. Sensitivity, specificity and accuracy of VNC images for the characterization of lipid-poor adenomas were calculated from chi-square tables of contingency.

RESULTS

No significant differences were seen for mean CT values in normal adrenal tissue, adrenal adenoma and the muscles of posterior spine between TNC and VNC images (p>0.05), except the abdominal aortic and spleen which the mean CT values in VNC images was higher than that in TNC image and the differences were statistically significant (p<0.05). SNR of all tissues in VNC images were higher than that in TNC image, and the differences were statistically significant (p<0.05) expect the abdominal aortic (p>0.05). The subjective score of VNC images was lower than that of TNC image, but the difference was no statistically significant (p>0.05). The radiation dose of VNC images was lower than that of TNC (p<0.05). A positive correlation was found for CT values of adrenal adenoma between TNC and VNC images. Sensitivity, specificity, and accuracy from VNC images of arterial phase for the characterization of lipid-poor adenoma were 86.9%, 100%, 90.3% and from venous phase were 60.9%, 87.5%, 67.7%.

CONCLUSION

VNC images calculated from contrast-enhanced dual-energy CT have a potential to replace the TNC images to diagnose the adrenal adenoma and thus reduce the patient’s radiation dose.

CLINICAL RELEVANCE/APPLICATION

Dual-energy VNC have a potential to replace the TNC images to diagnose the adrenal adenoma and thus reduce the patient’s radiation dose.

PURPOSE

To characterize adrenal lesions as benign or malignant on contrast-enhanced dual energy CT using material suppression imaging (MSI) virtual unenhanced images and pseudo-unenhanced monoenergetic 140 keV images.

METHOD AND MATERIALS

IRB-approved HIPAA-compliant study. A retrospective search identified consecutive adult outpatients who had undergone multiphasic dual energy CT (DECT) with an adrenal lesion (≥1 cm) reported. Two patients weighing ≥300 lbs were excluded. A single board-certified radiologist reviewed the CTs and placed ROIs on the adrenal lesions on the noncontrast (NC) series and simultaneously placed matching ROIs on MSI virtual unenhanced and virtual monoenergetic 140 keV images. The lesions were characterized by accepted clinical standards. Spearman rank correlation was performed to evaluate for associations between the virtual unenhanced, pseudo-unenhanced HU and NC HU and t tests to evaluate means. Regression analysis was performed to identify threshold values to characterize adrenal lesions as benign vs malignant. Myelolipomas were excluded from the regression analysis.

RESULTS

104 patients (52M, 52F, mean age 62, weight 188 lb) with a total of 140 adrenal lesions were identified. 56%(78/140) of the lesions were lipid-rich adenomas, 6%(9/140) lipid-poor adenomas, 20%(28/140) malignancies, 8%(11/140) myelolipomas and 10%(14/140) indeterminate. The mean HUs for adenomas were -6.5 (NC), 11.3 (MSI), 12.5 (140 keV); mean HUs for malignant lesions were 34.2 (NC), 39.1 (MSI) 38.7 (140 keV), all p<0.0001. There were very strong Spearman correlations between NC and MSI HU (.83), NC and 140keV HU (.81) and MSI and 140keV HU (98). Excluding 1 obvious necrotic RCC metastasis, a threshold of 20 HU on MSI and 16 HU on 140keV images correctly characterizes lesions as adenomas with a sensitivity of 68%(59/87) and 53%(46/87), respectively, both with specificity of 100%.

CONCLUSION

MSI virtual unenhanced and virtual 140keV monoenergetic contrast-enhanced DECT images can be used to characterize adrenal adenomas with a sensitivity of 72% and 59%, respectively, when using new HU threshold values of 20 and 16, respectively. Excluding an obvious necrotic RCC metastasis, both threshold values are 100% specific.

CLINICAL RELEVANCE/APPLICATION

In this largest DECT series of adrenal lesions, new HU criteria are presented that can characterize lesions on contrast-enhanced DECT, potentially obviating the need for further imaging for most patients.

SSA10-06 Added Value of Spectral CT Imaging in Differential Diagnosis of Lipid-poor Adrenal Adenomas and Pheochromocytomas
To investigate spectral CT imaging features of lipid-poor adrenal adenoma and pheochromocytoma and to assess the value of spectral CT for differentiating them.

**METHOD AND MATERIALS**

This was a retrospective study with images from a radiology database. 18 pathologically proven pheochromocytomas were compared with 30 lipid-poor adrenal adenomas (unenhanced attenuation >10HU, absolute washout >60% or relative washout >40% and absence of clinical indicators of pheochromocytoma). Patients underwent arterial phase (AP) and portal venous phase (PP) scans with dual energy spectral CT (DEsCT) mode. Both the material-decomposition images, and monochromatic image sets with photon energies from 40 to 140keV were reconstructed. Quantitative parameters [CT number as function of photon energies and normalized iodine concentration (NIC) for the two lesion types] were calculated and compared using two-sample t test. Two readers blinded to the pathologic results qualitatively assessed lesion types using the conventional CT characteristics. Sensitivity and specificity were compared between the qualitative and quantitative studies.

**RESULTS**

Mean tumor size of lipid-poor adrenal adenomas and pheochromocytomas was 2.3cm and 3.2cm, respectively. Pheochromocytomas had higher CT number than lipid-poor adrenal adenomas at every energy levels in both AP and PP (p<0.05), with greater differences at lower energies. NIC values were lower in lipid-poor adrenal adenomas than in pheochromocytomas: 0.16±0.08 vs. 0.32±0.14 in AP, p<0.001 and 0.45±0.16 vs. 0.62±0.23 in PP, p=0.012. The quantitative NIC measurements provided higher sensitivity (82.4%) and specificity (85.2%) for differentiating lipid-poor adrenal adenoma from pheochromocytoma compared with those (72.2% and 60.0%, respectively) of conventional qualitative CT image analysis.

**CONCLUSION**

The lipid-poor adrenal adenoma and pheochromocytoma had distinctively different characteristics on CT spectral imaging. NIC obtained in spectral CT imaging provided the highest sensitivity and specificity for the differential diagnosis between lipid-poor adrenal adenoma and pheochromocytoma.

**CLINICAL RELEVANCE/APPLICATION**

The lipid-poor adrenal adenoma and pheochromocytoma had distinctively different characteristics on CT spectral imaging.

**SSA10-07 MASS Criteria as a Predictor of Survival in Sunitinib Treated Metastatic RCC - A Secondary Post-hoc Analysis of a Multi-institutional Prospective Phase III Trial**

To validate MASS Criteria as a predictive imaging biomarker in metastatic RCC treated with anti-angiogenic therapy.

**METHOD AND MATERIALS**

As part of a published multi-institutional prospective phase III trial, 375 adult patients with metastatic clear cell RCC were treated with sunitinib. In this secondary post-hoc retrospective analysis, initial post-therapy CT images were evaluated by RECIST, Choi Criteria, and MASS Criteria in patients with DICOM format images. Comparison of PFS and OS among MSKCC risk and imaging response groups was evaluated using log-rank test. Inter-observer agreement between 3 readers was assessed in 21 randomly selected cases using intra-class correlation coefficient (ICC).
Twelve renal lesions (11 clear cell RCCs and 1 chromophobe RCC) were evaluated in 12 patients. All ccRCCs showed defect of tumors' pseudo-capsule, for combination of T2-weighted images and ASL, the hypo signals in T2-weighted images as well hyper signals in perfusion images was defined as the defect of tumors' pseudo-capsule. The diagnostic performance was determined on a pixel by pixel basis. For T2-weighted images alone, the discontinuous hypo signal intensity rim was defined as the defect of tumors' pseudo-capsule. For perfusion imaging, renal blood flow (RBF) was quantitatively measured on the perfusion images which were assessed using diagnostic test's index. A modified Look-Locker inversion-recovery (MOLLI) sequence was used for T1 mapping. To evaluate the role of CT Texture analysis in prediction of progression free and overall survival and assessment of response to treatment with Sunitinib in patients with metastatic clear renal cell carcinoma (RCC), Contrast enhanced CT texture parameters were assessed in 40 patients with metastatic clear RCC who were treated with Sunitinib. Appropriate measurable lesions were selected based on RECIST criteria before and about two months after treatment with Sunitinib. Texture and histogram analysis of the lesions were performed using TexRad software. Using a Cox regression model, correlation of texture parameters with measured time to progression and overall survival were assessed. "Size normalized tumor Entropy" (NE) was found as an independent predictor of time to progression and overall survival and can add to Heng; a well-known prognostic model for metastatic RCC patients. Cox proportional hazards regression analysis (HR) showed that NE was an independent predictor of time to progression. (HR = 0.01 and 0.02; 95% confidence intervals (CI): 0.00 - 0.29 and 0.00 - 0.39; p=0.01 and p=0.01 for NE before and two months after treatment, respectively). NE was also shown to be an independent predictor of overall survival. (HR = 0.01 and 0.01; 95% CI: 0.00 - 0.31 and 0.001 - 0.22; p=0.01 and p=0.003 for NE before and two months after treatment, respectively). Tumor heterogeneity is a well-known feature of malignancy reflecting areas of increased cellular density, hemorrhage and necrosis. CT texture analysis can quantify heterogeneity by using a range of parameters including size normalized Entropy (NE) as a measure of texture irregularity. Our study showed that NE was an independent predictor of the outcome of treatment with Sunitinib in patients with metastatic RCC and can be used for prediction of time to progression and overall survival in these patients. This can help identify non-responders from the outset with the potential to avoid unnecessary toxicity and to start alternative therapies earlier. The ability to identify poor responders early in the course of treatment or before starting the treatment can help patients be spared from toxicity usually associated with these treatments and could potentially receive alternative therapies earlier. Using the costly drugs of treatment only in patients who benefit from them will be a potential for cost-effectiveness improvement. To evaluate the role of CT Texture analysis in prediction of progression free and overall survival and assessment of response to treatment with Sunitinib in patients with metastatic clear renal cell carcinoma (RCC), Contrast enhanced CT texture parameters were assessed in 40 patients with metastatic clear RCC who were treated with Sunitinib. Our study showed that NE was an independent predictor of the outcome of treatment with Sunitinib in patients with metastatic RCC and can be used for prediction of time to progression and overall survival in these patients. This can help identify non-responders from the outset with the potential to avoid unnecessary toxicity and to start alternative therapies earlier. The ability to identify poor responders early in the course of treatment or before starting the treatment can help patients be spared from toxicity usually associated with these treatments and could potentially receive alternative therapies earlier. Using the costly drugs of treatment only in patients who benefit from them will be a potential for cost-effectiveness improvement. To evaluate the role of CT Texture analysis in prediction of progression free and overall survival and assessment of response to treatment with Sunitinib in patients with metastatic clear renal cell carcinoma (RCC), Contrast enhanced CT texture parameters were assessed in 40 patients with metastatic clear RCC who were treated with Sunitinib. Appropriate measurable lesions were selected based on RECIST criteria before and about two months after treatment with Sunitinib. Texture and histogram analysis of the lesions were performed using TexRad software. Using a Cox regression model, correlation of texture parameters with measured time to progression and overall survival were assessed. "Size normalized tumor Entropy" (NE) was found as an independent predictor of time to progression and overall survival and can add to Heng; a well-known prognostic model for metastatic RCC patients. Cox proportional hazards regression analysis (HR) showed that NE was an independent predictor of time to progression. (HR = 0.01 and 0.02; 95% confidence intervals (CI): 0.00 - 0.29 and 0.00 - 0.39; p=0.01 and p=0.01 for NE before and two months after treatment, respectively). NE was also shown to be an independent predictor of overall survival. (HR = 0.01 and 0.01; 95% CI: 0.00 - 0.31 and 0.001 - 0.22; p=0.01 and p=0.003 for NE before and two months after treatment, respectively). Tumor heterogeneity is a well-known feature of malignancy reflecting areas of increased cellular density, hemorrhage and necrosis. CT texture analysis can quantify heterogeneity by using a range of parameters including size normalized Entropy (NE) as a measure of texture irregularity. Our study showed that NE was an independent predictor of the outcome of treatment with Sunitinib in patients with metastatic RCC and can be used for prediction of time to progression and overall survival in these patients. This can help identify non-responders from the outset with the potential to avoid unnecessary toxicity and to start alternative therapies earlier. The ability to identify poor responders early in the course of treatment or before starting the treatment can help patients be spared from toxicity usually associated with these treatments and could potentially receive alternative therapies earlier. Using the costly drugs of treatment only in patients who benefit from them will be a potential for cost-effectiveness improvement. tumors’ pseudo-capsule on T2-weighted images. Of the 11 ccRCCs cases, 10 cases showed blood flow right on the defect area of tumors’ pseudo-capsule on perfusion images and 1 case did not. All the defect areas of tumors’ pseudo-capsule seen in the surgery operation had renal capsule invasion. For defecting of tumors’ pseudo-capsule, i.e. predicting renal capsule invasion, sensitivity, specificity, positive predictive value and negative predictive value were 100%, 33.3%, 81.8%, 100% for T2-weighted images alone and 100%, 66.7%, 90%, 100% for combination of T2-weighted images and ASL images.

CONCLUSION

The combination of T2-weighted images and ASL images produced promising diagnostic accuracy for predicting renal capsule invasion, which could offer additional imaging information for clinical diagnosis of renal tumors.

CLINICAL RELEVANCE/APPLICATION

Noninvasively and prospectively evaluated the presence of the defect pseudo-capsule in renal tumors may help predict the invasiveness of tumor and influence clinical therapy strategy.

**Prophylactic Antibiotics during Totally Implantable Venous Access Device Placement Does Not Decrease the Rate of Infection**

Sunday, Nov. 29 10:45AM - 10:55AM Location: E350

**Participants**
Jonathan Jo, New York, NY (Presenter) Nothing to Disclose
Bradley B. Pua, MD, New York, NY (Abstract Co-Author) Nothing to Disclose

Ronald S. Winokur, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
David C. Madoff, MD, New York, NY (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
Controversy still exists regarding antibiotic use in totally implantable venous access device (TIVAD) placement. A recent study showed a <1% risk of catheter related bloodstream infection (CLABSI) without the use of antibiotic prophylaxis. The current study seeks to delineate the efficacy of prophylactic antibiotics in TIVAD placement and to identify parameters associated with infection risk in an institution where antibiotic prophylaxis was used in the majority of cases.

**METHOD AND MATERIALS**
Following IRB approval, retrospective review of consecutive patients receiving TIVADs from January 2008 - December 2012 were analyzed for port infections. Post-procedural infection was defined as port removal within 30 days of placement with clinical signs of infection. Demographic information, comorbidities, hospital admission status, port characteristics, as well as prophylactic and supplemental antibiotic use were documented. Preoperative laboratory results were reviewed for white blood cell count (WBC), platelet count, and coagulation studies. Chi-square tests were used to determine associations between patient characteristics and procedural infection.

**RESULTS**
Of 1438 patients, 1158 (80.5%) received antibiotics and 280 (19.5%) did not. Of the patients given antibiotics, 143 (12.3%) also received supplemental antibiotics within 30 days of port placement and were excluded from analysis. Among the remaining 1295 patients, 7 post-procedural infections were identified (0.5%), all occurring in the antibiotic group (p<0.0001). Post-procedural infection was also significantly associated with inpatient status versus outpatient (3.8% vs. 0.1%, p<0.0001) and double lumen ports versus single lumen (1.9% vs. 0.2%, p=0.002).

**CONCLUSION**
Prophylactic antibiotic therapy does not reduce the post-procedure infection rate. Infection rates are higher with inpatients and those receiving double lumen ports.

**CLINICAL RELEVANCE/APPLICATION**
With level 8 evidence in existence, the Society of Interventional Radiology guidelines suggests that prophylactic antibiotics are unnecessary for tunneled central lines. No consensus exists for totally implantable venous access devices. Despite mounting evidence of the limited utility of antibiotics, many interventional radiologists and the majority of fellows of the American College of Surgeons still use antibodies. The study seeks to add to the evidence that prophylactic antibiotics may not add benefit in this setting.

**Developing a Method for Testing Mechanical Properties for Implantable Catheter Lines**

Sunday, Nov. 29 10:55AM - 11:05AM Location: E350

**Participants**
Jasmin D. Busch, MD, Hamburg, Germany (Presenter) Nothing to Disclose
Henning Schroder, Hamburg, Germany (Abstract Co-Author) Nothing to Disclose
Kay Sellenschloh, Hamburg, Germany (Abstract Co-Author) Nothing to Disclose
Gerhard Huber, Hamburg, Germany (Abstract Co-Author) Speakers Bureau, Ulrich GmbH & Co KG;
Gerhard B. Adam, MD, Hamburg, Germany (Abstract Co-Author) Nothing to Disclose
Harald Ittrich, MD, Hamburg, Germany (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
To develop a reproducible and sensitive method for the quantification of parameters of mechanical properties of catheter lines as well as to investigate the influences of artificial aging.

**METHOD AND MATERIALS**
Constructing an experimental setup and performing uniaxial tensile tests with 5F-silicone- and 6F-polyurethane catheter lines. Subgroups were each with unattended (n=6), chemically aged (n=7), and mechanically aged samples. Material behavior was analyzed by optical strain measurement (EOS 700D, Canon, Tokio/ Japan) and force measuring system (Xforce F, Zwick Roell AG, Ulm/ Germany). Maximum force (N), stress at break (Pa), strain at break (%), and Young’s elastic modulus (Pa) were evaluated.

RESULTS
In the 5F-silicone catheter trial series ANOVA shows significant differences in subgroups with Young’s elastic module (p<0.001); in the 6F-polyurethan catheters with Young’s elastic module (p<0.001) maximum force (p<0.001), stress at break (p<0.001), as well as strain at break (p=0.001).

CONCLUSION
We successfully developed an experimental setup to quantify mechanical properties of various catheter lines and proofed reliability and sensitivity to determine artificial aging induced modification. The low range of variance promises to detect even minor deviations in material features.

CLINICAL RELEVANCE/APPLICATION
According to recurrent failures with catheter lines among the patient cohort with totally implanted port systems within our medical center it is necessary to gain knowledge about influences of long-term usage and to quantify aberrations to avoid risk owing to material fatigue or potentially faulty batches.

SSA23-03 Adrenal Venous Sampling in Primary Aldosteronism: Value of a Multinomial Regression Model to Detect Aldosterone Hypersecretion Lateralization When the Right Adrenal Vein Sampling is Missing

PURPOSE
To assess the value of a multinomial regression model to detect aldosterone hypersecretion lateralization (AHL) with adrenal venous sampling (AVS) when the right adrenal vein sampling is missing.

METHOD AND MATERIALS
All consecutive AVS from November 1990 to December 2014 were included. Non selective AVS, repeated AVS and AVS with missing data were excluded. Cortisol and aldosterone levels were measured simultaneously from the adrenal veins and left iliac vein before (basal) and after intravenous cosyntropin injection. Reference standard for AHL was a basal adrenal vein aldosterone /cortisol ratio (A/C) >4 the opposite side. Two multinomials regressions models were built to predict AHL (right, left or no lateralization) using only basal and after intravenous cosyntropin injection. AHL detection accuracy was assessed with receiver operating characteristic (ROC) curves.

RESULTS
AVS of 171/186 (91.9%) patients (60 women; 126 men, mean age 53.5 years) met the inclusion/exclusion criteria. AHL was found in 106 (62%) patients. Areas under the ROC curves for AHL detection with the basal and the post-cosyntropin models were respectively 0.907 (95%CI; 0.862-0.952) and 0.928 (95%CI; 0.892-0.965) for the right side (p=0.11) and 0.915 (95%CI; 0.872-0.958) and 0.917 (95%CI; 0.875-0.959) for the left side (p=0.84). Sensitivities to detect AHL with a specificity of 95% with the basal and the post-cosyntropin models were respectively 52.7% (95%CI; 38.9%-66.1%) and 56.4% (95%CI; 42.4%-69.4%) for the right side and 52.9% (95%CI; 38.6%-66.8%) and 59.2% (95%CI; 44.2%-72.7%) for the left side. There were no contralateral AHL among false positives in both models.

CONCLUSION
Multinomial regression models of AVS can determine AHL in the majority of patients even when the right adrenal vein sampling is missing. Basal and post cosyntropin multinomial regression models had similar accuracy to detect AHL.

CLINICAL RELEVANCE/APPLICATION
Adrenal venous sampling is essential to assess aldosterone hypersecretion lateralization before adrenalectomy but is limited by a high right adrenal vein cannulation failure rate.

SSA23-04 Selective Arterial Calcium Stimulation (SACST) with Hepatic Venous Sampling Differentiates Occult Insulinoma from Nesidioblastosis in Patients with Endogenous Hyperinsulinemic Hypoglycemia and Negative or Inconclusive Noninvasive Imaging

Sunday, Nov. 29 11:15AM - 11:25AM Location: E350

Participants
Scott M. Thompson, MD,PhD, Rochester, MN (Presenter) Research collaboration, Synta Pharmaceuticals Corp
Adrian Vella, Rochester, MN (Abstract Co-Author) Nothing to Disclose
F J. Service, Rochester, MN (Abstract Co-Author) Nothing to Disclose
PURPOSE
To determine the diagnostic role of selective arterial calcium stimulation (SACST) with hepatic venous sampling in differentiating occult insulinoma from nesidioblastosis in patients with hyperinsulinemic hypoglycemia and negative or inconclusive noninvasive imaging.

METHOD AND MATERIALS
An IRB-approved retrospective review was undertaken of 116 patients with biochemical evidence of endogenous hyperinsulinemic hypoglycemia, negative or inconclusive noninvasive imaging and surgically and pathologically confirmed occult insulinoma (N=42) or nesidioblastosis (N=74) who underwent SACST with hepatic venous sampling from 1/1996 to 3/2014. Clinical, laboratory, radiologic and pathology data were reviewed. The maximum hepatic venous insulin concentration (mHVI; μIU/m) and relative-fold increase in hepatic venous insulin concentration over baseline (rHVI) following calcium injection from the dominant artery were compared between insulinoma and nesidioblastosis groups. ROC curves were generated to determine the specificity of mHVI and rHVI in differentiating insulinoma from nesidioblastosis.

RESULTS
The biochemical results of SACST were positive (>2.0-fold) in two or more arterial distributions in 26.2% of patients in the insulinoma group and 73.0% of patients in the nesidioblastosis group (p<0.0001). The mean (±SEM) mHVI post calcium injection was significantly higher in the insulinoma group compared to the nesidioblastosis group (778.6 ± 189.6 μIU/m vs. 36.2 ± 4.1 μIU/m, respectively; p<0.001). The mean (±SEM) rHVI from baseline was significantly higher in the insulinoma compared to the nesidioblastosis group (25.1 ± 4.4 vs. 6.4 ± 0.5, respectively; p<0.001). The area under the receiver operator curve (AUC) for mHVI and rHVI was excellent (0.94; p<0.0001) and good (0.83; p<0.0001), respectively. mHVI cutoffs of >91.5μIU/m and >263.5μIU/m were 95% and 100% specific for insulinoma, respectively. A 19.0-fold increase in rHVI over baseline was 99% specific for insulinoma.

CONCLUSION
These data suggest that the biochemical results of SACST can differentiate occult insulinoma from nesidioblastosis with high specificity in patients with hyperinsulinemic hypoglycemia and negative noninvasive imaging.

CLINICAL RELEVANCE/APPLICATION
SACST should be considered in patients with hyperinsulinemic hypoglycemia and negative noninvasive imaging to differentiate occult insulinoma from nesidioblastosis, thereby avoiding blind pancreatic exploration.

SSA23-05  Comparison of Inferior Vena Cava Filter Placement by Two Different Vascular Physician Specialties

Sunday, Nov. 29 11:25AM - 11:35AM  Location: E350

Participants
Matthew Neill, New York, NY (Presenter) Nothing to Disclose
Heams W. Charles, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
Eric T. Aaltonen, MD, MPH, New York, NY (Abstract Co-Author) Nothing to Disclose
Amy R. Deipolyi, MD, PhD, New York, NY (Abstract Co-Author) Nothing to Disclose

PURPOSE
To compare inferior vena cava filter (IVCF) placement procedures performed by vascular-interventional radiology (VIR) to those by vascular surgery (VS) with respect to radiation exposure, procedure time, anesthesia, and filter position.

METHOD AND MATERIALS
All IVCF placements using contrast venography by VIR or VS in 2014 in a single tertiary hospital center were identified by a PACS database search. The operator, filter type, angulation and distance from the lowest renal vein, radiation dose, fluoroscopy time, and anesthesia type were noted. Angulation was measured as the angle between the midline of the IVC and centerline of the filter.

RESULTS
Of 176 IVCF placements performed in VIR in 2014, carbon dioxide venography was used in 15 cases which were excluded. One case was a combined retrieval and placement and was also excluded, resulting in 160 cases for analysis. A total of 21 filters were placed by VS in 2014; 5 were placed as a part of another fluoroscopic procedure and were excluded from dose and fluoroscopy time analysis. Among the 160 cases performed by VIR, 152 were performed with topical access site anesthesia only; 2 with nursing-administered intravenous sedation; and 6 with anesthesia. By comparison, all 21 cases by VS were performed with anesthesia. Comparing cases performed by VS and VIR, mean radiation dose was higher (180 vs. 66 mGy; p=0.001), fluoroscopy time longer (4.6 vs. 2.5 minutes; p=0.0009), and filter angulation greater (3.8 vs. 2.5 degrees; p=0.006), respectively. There was no statistically significant difference in distance of the filter tip from the most inferior renal vein (1.7 vs. 1.1 cm; p=0.19).

CONCLUSION
IVCF placement by VIR, compared to VS, entails less radiation exposure, less procedure time as indicated by lower fluoroscopy times, less need for anesthesia consultation, and more precise placement centered in the IVC.

CLINICAL RELEVANCE/APPLICATION
Demonstrating superior technique and lower procedure cost is essential in promoting VIR practice development. IVCF filter placement performed by interventional radiologists is faster, involves less radiation exposure, and reduces need for anesthesiology consultation, compared to filter placement by vascular surgery.

SSA23-06  Up to 96% Dose Reduction in Pediatric and Young Adult Venous Interventions: Too Good to Be True?
Participants
Timothy Singewald, MD, Cincinnati, OH (Presenter) Nothing to Disclose
Rami Nachabe, PhD, Best, Netherlands (Abstract Co-Author) Employee, Koninklijke Philips NV
Nicole Hilvert, Cincinnati, OH (Abstract Co-Author) Nothing to Disclose
John M. Bardio, MD, Cincinnati, OH (Abstract Co-Author) Research Consultant, Koninklijke Philips NV; Travel support, Koninklijke Philips NV
Manish N. Patel, DO, Cincinnati, OH (Abstract Co-Author) Nothing to Disclose

PURPOSE
The purpose of this study is to evaluate dose reductions achieved during venous interventions such as IVC filter placement/retrieval and thrombolysis performed on an enhanced low-dose interventional radiology system.

METHOD AND MATERIALS
An IRB approved retrospective review of patients who underwent a relatively low-dose venous procedure (IVC filter placement/retrieval) or a relatively high-dose venous intervention (lower extremity thrombolysis) was performed. Radiation doses for cases performed on an enhanced low-dose interventional system (AlluraClarity, Philips Healthcare, Best, The Netherlands) were compared with cases from our former system used as a reference (AlluraXper, Philips Healthcare, Best, The Netherlands). Nineteen IVC filter placements or retrievals (5 male/7 female, 9-35 years, 37-84 kg) were performed on the low-dose system and were compared with 21 cases (4 male/10 female, 13-31 years, 49-112 kg) on the reference system. Twelve thrombolysis cases (3 male/4 female, 15-18 years, 51-77 kg) performed on the low-dose system were compared with 12 cases (0 male/5 female, 14-18 years, 53-146 kg) on the reference system.

RESULTS
Overall radiation doses were substantially reduced using the low-dose system compared to the reference system (the following doses are reported as low-dose vs reference system). For IVC filter placement/retrieval, median cumulative procedure dose-area product (DAP) was 3.5 vs 30.9 Gy.cm² (89% dose reduction), fluoroscopy dose/minute was 1.06 vs 3.21 Gy.cm²/min (67% dose reduction), and the digital subtraction angiography (DSA) dose/frame was 0.03 vs 0.72 Gy.cm²/frame (96% dose reduction). For thrombolysis, median cumulative procedure DAP was 25 vs 409 Gy.cm² (94% dose reduction), fluoroscopy dose/minute was 1.4 vs 5.2 Gy.cm²/min (73% dose reduction), and the DSA dose/frame was 0.06 vs 1.6 Gy.cm²/frame (96% dose reduction).

CONCLUSION
Significant radiation dose reduction is possible in pediatric and young adult patients undergoing venous interventions by using an enhanced low-dose interventional radiology system.

CLINICAL RELEVANCE/APPLICATION
Use of an enhanced low-dose interventional radiology system for venous interventions results in substantial dose reduction of up to 96% for pediatric and young adult patients.

SSA23-07 Balloon Pulmonary Angioplasty: Applicability of Fluoroscopy-based Registration of a Pre Acquired C-Arm CT for Procedure Guidance

Sunday, Nov. 29 11:45AM - 11:55AM Location: E350

Participants
Jan Hinrichs, MD, Hannover, Germany (Presenter) Nothing to Disclose
Christian Von Falck, MD, Hannover, Germany (Abstract Co-Author) Research Grant, Pro Medicus Limited Research Grant, Siemens AG
Marius Hoepfer, Hannover, Germany (Abstract Co-Author) Nothing to Disclose
Julius Renne, MD, Hannover, Germany (Abstract Co-Author) Nothing to Disclose
Karen Olsen, Hannover, Germany (Abstract Co-Author) Nothing to Disclose
Frank K. Wacker, MD, Hannover, Germany (Abstract Co-Author) Research Grant, Siemens AG Research Grant, Pro Medicus Limited
Bernhard C. Meyer, Hannover, Germany (Abstract Co-Author) Research Consultant, Pro Medicus Limited

PURPOSE
To investigate the use of a fluoroscopy-based registration of a pre acquired C-Arm CT (CACT) for procedure guidance in patients suffering from chronic thromboembolic pulmonary hypertension (CTEPH) undergoing balloon pulmonary angioplasty (BPA).

METHOD AND MATERIALS
42 BPA procedures performed in 27 CTEPH patients (9m, 70±14y) were included in this study. Twenty-two BPAs were guided by selective CACT (syngo DynaCT, Artis Q®, Siemens Healthcare, Forchheim, Germany) acquired immediately before BPA (G3D). In another twenty BPAs (G2D), two orthogonal fluoroscopic images of the chest where acquired semi-automatically matched with a product (DAP) was 3.5 vs 30.9 Gy.cm² (89% dose reduction), fluoroscopy dose/minute was 1.06 vs 3.21 Gy.cm²/min (67% dose reduction), and the digital subtraction angiography (DSA) dose/frame was 0.03 vs 0.72 Gy.cm²/frame (96% dose reduction). For thrombolysis, median cumulative procedure DAP was 25 vs 409 Gy.cm² (94% dose reduction), fluoroscopy dose/minute was 1.4 vs 5.2 Gy.cm²/min (73% dose reduction), and the DSA dose/frame was 0.06 vs 1.6 Gy.cm²/frame (96% dose reduction).

RESULTS
Overall, 143 SPA were intended to undergo BPA. Agreement of WP-P and WP-U was obtained in G3D 82% and G2D 86%. The guide wire was successfully placed in G3D 93% and G2D 94% and subsequent BPA was successfully performed in G3D 91% and G2D 94%. CACT post-processing took a mean of 8min G3D and 7min G2D. Overall intervention time was 126min G3D and 117min G2D. No severe reperfusion edema occurred and no patient needed mechanical/assisted ventilation. Dose-area product (DAP) was significantly higher for G3D (9289±4221 vs. G2D 5448±2629 µGym², p=0.002).

CONCLUSION
The use of fluoroscopy based 2D3D registration of CACT images for BPA guidance is feasible and accurate. 2D3D registration can be used to save radiation exposure if a pre-acquired CACT for guidance is available.

**CLINICAL RELEVANCE/APPLICATION**

CACT of the pulmonary arteries bares the opportunity to increase patient’s safety during BPA, when used as guidance method. Additionally, 2D3D fusion of pre-acquired CACT’s saves radiation dose in repeated BPAs.

**SSA23-08 Added Value of Fluoroscopy/Venography during Endovenous Laser Therapy for Symptomatic Varicose Veins**

**Sunday, Nov. 29 11:55AM - 12:05PM Location: E350**

Participants
Ricardo Yamada, MD, Charleston, SC (Presenter) Nothing to Disclose
J. Bayne Selby Jr, MD, Charleston, SC (Abstract Co-Author) Nothing to Disclose

John Selby III, Charleston, SC (Abstract Co-Author) Nothing to Disclose
James P. Gregg, MD, Houston, TX (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

Procedural difficulties or unexpected findings may occur during endovenous laser therapy of varicose veins using ultrasound alone. Fluoroscopy/venography can be a useful adjunctive modality.

**METHOD AND MATERIALS**

After IRB approval, EVLT performed in the last 10 years were reviewed. Fluoroscopy/venography and ultrasound were used in all cases. Images, procedure report and patient’s clinical condition were reviewed. Three graders evaluated whether this imaging method changed the treatment plan, aided completion of the procedure, displayed unexpected findings or clarified previous treatments results.

**RESULTS**

A total of 169 treatments were identified, in 142 patients. Fluoroscopy/venography had impact in 67 procedures (39%). In 25 cases it clarified multiple complex collateral veins. In 23 cases it helped navigate the guide-wire. In 16 cases it identified duplicated/accessory veins. In 3 cases it identified the need for second access. 23 patients had prior surgical ligation/stripping, sclerotherapy or endovenous thermal ablation. Among them fluoroscopy/venography contributed to procedure completion in 18 patients (78%).

**CONCLUSION**

Fluoroscopy/venography were helpful in patients previously treated, in whom passage of the guide wire was difficult and in those with bifurcated/accessory veins. Of these, patients with prior treatment benefited the most from fluoroscopy/venography.

**CLINICAL RELEVANCE/APPLICATION**

Fluoroscopy/venography during EVLT is particular helpful in patients with recurrent varicose veins after prior treatment. This additional imaging modality may be considered in all patients undergoing repeated treatment.

**SSA23-09 Large Primary Varicose Veins: Combined Ultrasound Guided Endo-venous Laser Therapy and Selective Surgical Ligation at Sephano-Femoral Junction-A Mean 7 Years Follow-up with Review of Literature**

**Sunday, Nov. 29 12:05PM - 12:15PM Location: E350**

Participants
Kiran C. Patil JR, MD, Jalgaon, India (Presenter) Nothing to Disclose
Anurag Singh, MBBS, MD, Sharjah, United Arab Emirates (Abstract Co-Author) Nothing to Disclose
Rajesh D. Jawale, MBBS, MD, Nasik, India (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

1) To evaluate our experience and curative effect of the combination of ultrasound guided endovenous Laser therapy (EVLT) and surgical detail separate ligation of each tributaries at S-F junction. 2) To review our experience with mean 7 years followup. 3) To compare our results with reviewed literature.

**METHOD AND MATERIALS**

Over the period from Jan 2005 to Dec 2013, 118 patients with 135 limbs were identified to have symptomatic primary large varicose veins (Criteria was SF junction diameter > 10 mm and saphenous vein > 8mm) were treated with this combined approach. Separate surgical ligation of each tributary at SF junction followed by ultrasound guided EVLT of rests of the lower limb large tributaries, duplicated veins and short saphenous vein (SSV) done by using 980-nm pulse wave Laser. Superficial subcutaneous tunnelsent injection of saline to prevent skin complications was used. Principal outcome measures were abolition of reflux, cosmetic improvement and improvement in Aberdeen Varicose Veins Symptom Score (AVVSS). Future follow up on duplex ultrasound at week 1, months 1, 3, 6 then yearly for mean of 7 years.

**RESULTS**

The procedure was technically successful in all cases. Spot skin burns in 2, short term peri ankle parasthesia in 25, recurrent minor tributaries and spider veins in 12, 4 patients developed new parallel GSV. 2 patient developed significant recurrence. All results were much better than only laser or only surgical or other combined methods reviewed in literature.

**CONCLUSION**

This combination therapy of intervention radiology and local surgery in treatment of large primary varicose veins appears to be very
This combination therapy of intervention radiology and local surgery in treatment of large primary varicose veins appears to be very effective and safe approach. Its long term outcome is more superior and well accepted by patients than the other traditional methods compared from literature.

**CLINICAL RELEVANCE/APPLICATION**

Combined surgical and endovenous approach appears promising in good outcome in large primary varicose veins treatments. Large primary varicose veins of both lower limbs are often associated with Sephano-femoral (S-F) junction diameter and saphenous vein diameter larger than 10 mm with multiple large varicose tributaries. These are notorious for recurrence even after intervention or surgical treatment. Hence combined intervention radiological and surgical approach was selected to obtain the best long term results.
Breast Imaging (Contrast Mammo/CT)

Noha Abdel Shafey, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose

PURPOSE
Contrast-enhanced spectral mammography (CESM) is an advanced application of digital mammography that uses contrast agent. But little is known about its efficacy in Egyptian patients. In this work; we aimed to share our experience in evaluating large sector of female patients with different breast diseases using CESM.

METHOD AND MATERIALS
CESM was carried for 3000 patients during their daily visit to our institute from 2012-2014. Examinations were performed for staging of proved malignancy in 27% cases and to clarify nature of indeterminate lesions in another 30%. Post operative cases and follow up cases post neoadjuvant chemotherapy were 23% and 20% respectively. Medio-lateral oblique and cranio-caudal views were taken in low (22-33 kVp) and high (44-49 kVp) energy exposures after IV injection of non-ionic iodinated contrast agent. The diagnostic performance of the contrast enhanced mammography was evaluated and pathology from surgical specimen or ultrasound guided core biopsy were the gold standard of reference in all cases.

RESULTS
CESM presented sensitivity of 88% and specificity of 86% to differentiate benign and malignant masses. For post operative cases; sensitivity was 85% and specificity was 60%. In cases on chemotherapy; sensitivity was 87 % and specificity was 77%. Contrast uptake was noted in 2040/3000 (68%) lesions. Intense uptake and heterogeneous enhancement were more frequent in malignant pathology (p value ≤ 0.001). Uniform ring enhancement noted in cavitory benign masses as abscess cavities and infected cysts noted in 664 cases (22.1%). Multicentric and multifocal carcinomas were detected in 42.2% (n=1266) of proved malignant masses. Statistical analysis yielded a sensitivity, specificity and accuracy of 71.4%, 37.5% and 53.3% for conventional mammograms compared to 87.5 %, 75% and 80% for contrast enhanced mammograms respectively.

CONCLUSION
Contrast-enhanced spectral digital mammogram enhances the specificity of the standard mammogram. It presents an easy, simple and rapid contrast based method for discrimination between different breast pathologies and for follow up of chemotherapy and post operative cases.

CLINICAL RELEVANCE/APPLICATION
CESM represents a new era of imaging. It provides better diagnostic performance than the standard mammogram, perform proper screening for high risk patients and follow up response to different lines of management.

SSA01-02 Comparison of Background Parenchymal Enhancement on Contrast-Enhanced Spectral Mammography and Breast Magnetic Resonance Imaging

Sunday, Nov. 29 10:55AM - 11:05AM Location: Arie Crown Theater

Participants
Julie Sogani, MD, New York, NY (Presenter) Nothing to Disclose
Elizabeth A. Morris, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
Jennifer B. Kaplan, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
Donna D. D'Alessio, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
Debra A. Goldman, MS, New York, NY (Abstract Co-Author) Nothing to Disclose
Chaya Moskowitz, New York, NY (Abstract Co-Author) Nothing to Disclose
Maxine S. Jochelson, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
PURPOSE
The purposes of this study were to examine the extent of background parenchymal enhancement (BPE) on contrast-enhanced spectral mammography (CESM) and to compare the level of BPE on CESM and breast magnetic resonance imaging (MRI).

METHOD AND MATERIALS
This is a retrospective, IRB-approved and HIPAA-compliant study performed on women with or at increased risk for breast cancer who underwent screening CESM and MRI at our institution between 2010 and 2014. Need for informed consent was waived. Three readers independently rated the BPE level on each imaging modality using a categorical scale: minimal, mild, moderate, or marked.

RESULTS
A total of 278 women underwent both CESM and MRI within a median time interval of 0 days (range: 0-28 days). Of these women, the BPE level determined by the three readers was minimal in 41-43%, mild in 24-34%, moderate in 17-20%, and marked in 4-16% on CESM compared to 36-46% minimal, 24-38% mild, 16-23% moderate, and 5-14% marked on MRI. The majority of women had minimal or mild BPE both on CESM (68-76%) and MRI (69-76%). Between CESM and MRI, the agreement ranged from moderate for reader 3 (k=0.55, 95% CI: 0.47-0.63) to substantial for reader 1 (k=0.66, 95% CI: 0.57-0.75) and reader 2 (k=0.67, 95% CI: 0.60-0.75). Within CESM, the agreement for the readers was substantial at k=0.68 (95% CI: 0.62-0.73) with the pairwise agreement all being substantial (range: k=0.62-0.71). Within MRI, the agreement for the readers was substantial at k=0.75 (95% CI: 0.70-0.80) with the pairwise agreement all being substantial (range: k=0.72-0.79). Overall agreement on BPE levels between CESM and MRI and among the readers was substantial at k=0.66 (95% CI: 0.61-0.70).

CONCLUSION
The level of BPE detected on CESM is in substantial agreement with that on MRI. While increased BPE on MRI has been demonstrated to be associated with increased odds of breast cancer, additional studies will be needed to evaluate the role of BPE on CESM as a predictor of breast cancer risk.

CLINICAL RELEVANCE/APPLICATION
The level of BPE detected on CESM is in substantial agreement with that on MRI and may serve as an additional marker of breast cancer risk.

SSA01-03 The Correlation between the Mammographic Breast Density and the Intensity of Background Parenchymal Enhancement in Contrast Enhanced Spectral Mammography

Sunday, Nov. 29 11:05AM - 11:15AM Location: Arie Crown Theater

Participants
Rasha M. Kamal, MD, Cairo, Egypt (Presenter) Nothing to Disclose
Sahar Mansour, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Maha H. Helal IV, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Marwa A. Haggag, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Omnia Mokhtar, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Mohammed M. Gomaa, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose

PURPOSE
The purpose of this study is to assess the correlation between the mammographic breast density and the intensity of background parenchymal enhancement (BPE) on Contrast Enhanced Spectral Mammography (CESM).

METHOD AND MATERIALS
The study is a retrospective study that included 410 patients who underwent CESM. The mammographic breast density was assessed on the low-energy images and was graded on the basis of the ACR BI-RADS breast density categories from a to d. These were further grouped into: group 1 which included the fatty (a) and the scattered fibroglandular tissue (b) breast densities and group 2 which included the heterogeneously dense (c) and the extremely dense (d) breast densities. The intensity of BPE was assessed on the subtraction high-energy images and was scored on a 4-point scale on the basis of the ACR MRI BI-RADS criteria, as minimal, mild, moderate, or marked. Statistical correlation was calculated using the Pearson correlation coefficient.

RESULTS
A total of 278 women underwent both CESM and MRI within a median time interval of 0 days (range: 0-28 days). Of these women, 91/410 (22.2%) were included 203/410 (49.5%) cases out of which 91/203 (44.8%) cases showed minimal, 81/201 (40.3%) cases showed mild BPE. Only 2/207 (1%) and 1/207 (0.5%) cases showed moderate and marked BPE respectively. Group 2 (breast densities c and d) included 203/410 (49.5%) cases out of which 91/203 (44.8%) cases showed minimal, 81/203 (39.9%) cases showed mild, 24/203 (11.8%) cases showed moderate and only 7/203 (3.4%) cases showed marked BPE. The intensity of the BPE showed weak positive correlation with the corresponding breast density grade (r: 0.2824) were 376/410 (91.7%) of the cases showed minimal to mild BPE and only 34/410 (8.3%) showed moderate to marked BPE irrespective of the breast density group.

CONCLUSION
Mammographic breast density shows a weak positive correlation with the intensity of BPE on CESM. Most of the cases show lower scores of BPE irrespective of the corresponding breast density grade.

CLINICAL RELEVANCE/APPLICATION
Mammographic breast density shows weak positive correlation with the intensity of BPE on CESM. Most of the cases show lower scores of BPE, ranging from minimal to mild, irrespective of the corresponding breast density grade.
Increased mammographic density and marked BPE can both decrease mammography and MRI sensitivity and specificity as they can obscure subtle and minimally enhancing malignant breast lesions. The weak positive correlation between mammographic breast density and BPE in CESM is a major advantage. CESM can thus be considered in the screening and diagnostic work-up of high risk patients and those with a heterogeneous dense breast parenchyma.

**SSA01-04 Enhancement Patterns of Benign and Malignant Breast Lesions on Contrast-enhanced Breast Tomosynthesis**

Sunday, Nov. 29 11:15AM - 11:25AM Location: Arie Crown Theater

Participants
Chen-Pin Chou, MD, Kaohsiung, Taiwan (Presenter) Nothing to Disclose
Tsung-Lung Yang, MD,MD, Kaohsiung, Taiwan (Abstract Co-Author) Nothing to Disclose
Huay-Ben Pan, MD, Kaohsiung, Taiwan (Abstract Co-Author) Support, Hologic, Inc

**PURPOSE**
To assess the enhancement patterns of benign and malignant lesions on contrast-enhanced breast tomosynthesis (CEBT)

**METHOD AND MATERIALS**
Institutional review board approved the study. Written informed consent was obtained from all patients. A total of 140 consecutive women suspected of having architectural distortion on digital mammogram between March 2012 and April 2014 were reviewed. All women had both CEBT before biopsy. For the dual-energy CEBT, a modified Selenia Dimensions (Hologic, Inc.) machine was used. Simultaneously 2D mammogram and 3D tomosynthesis were taken after injection with iodine contrast agent. Post-contrast images were taken at 2 minutes (MLO view) and 4 minutes (CC view). The enhancement patterns were divided early enhancement in 2 minutes (type1), equal enhancement in 2 and 4 minutes (type2), late enhancement in 4 minutes (type3). The enhancement patterns were determined by consensus of two radiologists.

**RESULTS**
Total 151 histological results of breast lesions were available in 140 women (mean age 52 years, range 31-70 years). The pathology revealed 78 benign lesions and 73 breast malignancies (36 non-invasive and 37 invasive cancers). The enhancement patterns included 28 type 1, 65 type 2 and 58 type 3. Type 1 enhancement was found in 23 malignant lesions and 5 benign lesions, type 2 enhancement in 23 malignant lesions and 42 benign lesions, and type 3 enhancement in 27 malignant lesions and 31 benign lesions. Among 23 cancers with type 1 enhancement, 21 were invasive and 2 were non-invasive. Type 1 enhancement was highly associated with breast malignancy (p<0.01) and invasive breast cancer histology (p<0.01).

**CONCLUSION**
CEBT enhancement patterns in 2 and 4 minutes may predict the nature of breast lesions.

**CLINICAL RELEVANCE/APPLICATION**
Enhancement pattern of CEBT may play a role for differentiating breast lesions..

**SSA01-05 Contrast-enhanced Spectral Mammography versus Breast Tomosynthesis in Further Evaluation of Recalled Cases after Screening Mammograms**

Sunday, Nov. 29 11:25AM - 11:35AM Location: Arie Crown Theater

Participants
Norran H. Said, MD, FRCR, Cairo, Egypt (Presenter) Nothing to Disclose
Naglaa Abdel Razek, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Engy I. Ali, MSc, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Nivine A. Chalabi, MBCh, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Ashraf Selim, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
To compare the added value of Contrast Enhanced Spectral Mammography (CESM) and Breast Tomosynthesis (BT) in the confirmation or exclusion of breast cancer after their referral from the national screening program

**METHOD AND MATERIALS**
After Ethics committee approval, and patients’ consent, 75 women who underwent screening Digital mammography, and were recalled by two independent breast radiologists were enrolled in the study. All patients underwent both BT and CESM, and an independent BIRADS score was given for each modality. Results were compared to pathology and follow up of negative/ typically benign findings.

**RESULTS**
Out of the 75 patients; 39 were recalled due to detection of a mass, 19 due to focal asymmetry, 11 due to microcalcifications, and 6 due to architectural distortion. Sensitivity, Specificity, PPV, NPV, LR positive, LR negative of CESM were 91.1, 96.7, 97.6, 87.8, 27.3, 0.09 respectively, and in BT were 86.6, 76.6, 84.7, 79.3, 3.71, 0.17. Agreement by Kappa was 0.104. CESM and BT both agreed on TP in 36 cases out of 45 proved cancers. With CESM there were 4 FN cases, from which BT could detect 3 cancers (micro calcifications). With BT there were 6 FN cases from which CESM could detect 5 cancers. There was 1 FP by CESM, and 7 by BT. Biopsy was avoided by CESM in 29 cases, and by BT in 23 cases.

**CONCLUSION**
CESM was able to avoid/ confirm biopsy with diagnostic certainty apart from cases with only microcalcifications as the dominant finding, where BT has shown better diagnostic capabilities.

**CLINICAL RELEVANCE/APPLICATION**
Both CESM and BT are now valuable tools in the recall unit of a national screening program and have proven good clinical
CEBT and DCE-MRI showed similar diagnostic performance for architectural distortion lesions on screening mammogram.

CONCLUSION

the ROC curve (AUCs) for diagnosis of malignancy were not significantly different between CEBT and DCE-MRI (all p >0.05). For all readers, the areas under pathology revealed 24 benign lesions and 8 breast malignancies. The sensitivity/specificity/accuracy between CEBT and DCE-MRI

RESULTS

Total 32 histological results of architectural distortion were available in 32 women (mean age 54 years, range 45-63 years). The pathology revealed 24 benign lesions and 8 breast malignancies. The sensitivity/specificity/accuracy between CEBT and DCE-MRI for diagnosing breast cancers were 100%/38%/53% and 100%/58%/68%, respectively (all p>0.05). For all readers, the areas under the ROC curve (AUCs) for diagnosis of malignancy were not significantly different between CEBT and DCE-MRI (all p >0.05).

CONCLUSION

CEBT and DCE-MRI showed similar diagnostic performance for architectural distortion lesions on screening mammogram.

PURPOSE

To assess feasibility of automatic breast lesion classification algorithm in dual-energy contrast enhanced spectral mammography and evaluate its potential for biopsy sparing in benign breast lesions.

METHOD AND MATERIALS

A retrospective study, a set of 93 breast lesions in dual-energy contrast mammography, 41 benign,52 malignant lesions. Each lesion was manually contoured using standard PACS viewer drawing tools. Based on the data set a supervised learning algorithm was developed to tell benign and malignant lesions. The algorithm automatically extracts numerical descriptors from the pixels located inside and outside the lesion. The descriptors characterizes visual patterns that appear in benign and malignant lesion. The set of numerical descriptors is appended into a feature vector characterizing the lesion. In a training phase, a linear support vector machine classifier is trained to tell apart benign and malignant lesions using a subset of the lesions represented by their feature vectors and the corresponding label (benign/malignant) provided by pathology. In a testing phase, the remaining subset of lesions is fed to the trained classifier that returns a classification score. The higher the score, the higher the probability that the considered lesion is malignant. Eventually, the score is thresholded to provide the final classification with the desired balance between sensitivity and specificity. In the performed experiments, 92 lesions were used for training and 1 for testing phases. In this leave-one-out approach training and testing were repeated 93 times, each one for a different test lesion, so that each lesion was classified exactly 1 time without contributing to the training of its classifier.

RESULTS

Setting the classification score threshold (TH) to 0.5: sensitivity=0.90, specificity=0.76, NPV=0.86. Reducing TH to 0: sensitivity=0.98, specificity=0.54, NPV=0.96. Only 1 malignant lesion was classified as benign. Reducing TH to -0.5: sensitivity=1, specificity=0.37, NPV=1. It provides a reduction on 37% in biopsies without affecting sensitivity.

CONCLUSION

This research showed the feasibility of automatic lesion classification in dual-energy CESM with a significant potential to reduce the number of benign breast biopsies.

CLINICAL RELEVANCE/APPLICATION

Automatic lesion classification in dual-energy CESM has the potential to reduce the number of benign breast biopsies, therefore to reduce the anxiety of patients. And reduce the cost.

PURPOSE

To compare the diagnostic accuracy of contrast-enhanced breast tomosynthesis (CEBT) and dynamic contrast-enhanced breast MRI (DCE-MRI) for architectural distortion lesions on mammograms.

METHOD AND MATERIALS

Institutional review board approved the study. Written informed consent was obtained from all patients. A total of 32 consecutive women suspected of having architectural distortion on digital mammogram between March 2012 and April 2014 were reviewed. All women had both CEBT and DCE-MRI before biopsy. For the dual-energy CEBT, a modified Selenia Dimensions (Hologic, Inc.) machine was used. Simultaneously 2D mammogram and 3D tomosynthesis were taken after injection with iodine contrast agent and imaged between 2 and 4 minutes after injection. The BI-RADS classifications on CEBT were finally determined based on findings on combinations of 2D mammogram, 3D tomosynthesis and post-contrast subtraction 2D and 3D images. Women were also evaluated at 1.5T (GE) or 3T MRI (Siemens) with dedicated breast coil. Receiver operating characteristic (ROC) analysis was used to evaluate the performance of CEBT and DCE-MRI. Different radiologists interpreted CEBT and DCE-MRI.

RESULTS

Total 32 histological results of architectural distortion were available in 32 women (mean age 54 years, range 45-63 years). The pathology revealed 24 benign lesions and 8 breast malignancies. The sensitivity/specificity/accuracy between CEBT and DCE-MRI for diagnosing breast cancers were 100%/38%/53% and 100%/58%/68%, respectively (all p>0.05). For all readers, the areas under the ROC curve (AUCs) for diagnosis of malignancy were not significantly different between CEBT and DCE-MRI (all p >0.05).

CONCLUSION

CEBT and DCE-MRI showed similar diagnostic performance for architectural distortion lesions on screening mammogram.
CLINICAL RELEVANCE/APPLICATION

CEBT is a flexible imaging tool for differentiating architectural distortion lesions on screening mammogram.

SSA01-08  The Comparative Role of Contrast Enhanced Spectral Mammography versus Sono-mammography in the Assessment of Patients Following Breast Surgery

Participants
Marwa M. El Sayad, MB.Bch, Giza, Egypt (Presenter) Nothing to Disclose
Rasha M. Kamel, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose
Ayda A. Youssef, MD, Cairo, Egypt (Abstract Co-Author) Nothing to Disclose

PURPOSE

The purpose of this study is to evaluate the diagnostic accuracy of Contrast Enhanced Spectral Mammography as an adjunct to Sono-mammography versus Sono-mammography alone in the assessment of patients following breast surgery.

METHOD AND MATERIALS

The study is a prospective study that was approved by the research ethical committee of the Radiology Department. It included 38 patients (with 52 breast lesions) with history of breast surgery and indeterminate sono-mammographic findings. Patients with mastectomy bed lesions who could not perform mammography were excluded from the study. They were all scheduled for Contrast Enhanced Spectral Mammography (CESM). The identified lesions were classified into lesions at the site of the operative bed, lesions in the ipsilateral breast, yet, away from the operative bed and lesions in the contra-lateral breast. These lesions were further classified into benign or malignant by biopsy and histopathology. The sensitivity, specificity, positive and negative predictive values and likelihood ratios of sono-mammography and CESM were calculated and compared when using sono-mammography or CESM alone and when adding the three modalities together in diagnosis.

RESULTS

Out of the 52 identified breast lesions, 30/52, 57.7% were benign and 22/52, 42.3% were malignant. Eighteen out of 52 lesions, 34.6% were identified at the operative bed, 7/52, 13.5% in the ipsilateral breast, and 27/52, 51.9% in the contra-lateral breast. The calculated sensitivity, specificity, positive and negative predictive values and positive and negative likelihood ratios of sono-mammography were 81.8%, 23.3%, 43.9%, 63.6%, 1.067 and 0.779 respectively as compared to 86.4%, 90%, 86.4%, 90%, 8.636 and 0.152 for CESM. When adding CESM to sono-mammography the calculated diagnostic indices were raised to 95.5%, 96.7%, 95.5%, 96.7%, 28.636 and 0.047 respectively.

CONCLUSION

Adding CESM in the post-operative breast assessment improved the diagnostic performance of sono-mammography.

CLINICAL RELEVANCE/APPLICATION

The follow up of patients who had undergone breast surgery, especially the interpretation of findings of the postsurgical breast, represents a diagnostic dilemma. Many findings can be mistaken for cancer. CESM is a promising time saving and lower cost technique than Magnetic Resonance Imaging (MRI). It has the potential to replace MRI as an adjunct to sono-mammography in this field.

SSA01-09  Clinical Performance of Dedicated Breast Computed Tomography in Comparison to Diagnostic Digital Mammography

Participants
Elodia B. Cole, MS, Charleston, SC (Presenter) Consultant, FUJIFILM Holdings Corporation; Consultant, Koninklijke Philips NV; Consultant, Alan Penn & Associates, Inc
Srinivasan Vedantham, PhD, Worcester, MA (Abstract Co-Author) Nothing to Disclose

Andrew Karellas, PhD, Worcester, MA (Abstract Co-Author) Research collaboration, Koning Corporation

PURPOSE

To compare the clinical performance of a three-dimensional dedicated breast computed tomography system requiring no breast compression alone (dBCT), dBCT as adjunct to two-dimensional standard view screening mammography (SM), and two-dimensional diagnostic mammography (DxM).

METHOD AND MATERIALS

Eighteen radiologists interpreted 235 cases (52 negative, 104 benign, 79 cancer; 93/235 calcifications) that were randomly selected from 478 cases enrolled under 3 different clinical trial protocols, all in diagnostic population. Each case consisted of unilateral SM, DxM and dBCT images. Each case was randomized to 3 sessions and interpreted under 3 conditions: dBCT alone, dBCT plus SM, and DxM alone with at least a 4-week washout period. Each interpretation included an overall BIRADS score and continuous probability of malignancy (POM) score. For each case, any identified lesion assigned BIRADS category 3 or greater had its location, type, BIRADS and POM reported. Sensitivity, specificity and area under the ROC curve (AUC) were determined with either pathology or 1-year follow-up as truth.

RESULTS

All reported performance metrics were averaged across all readers. Results are reported from analysis using BIRADS score after
The sensitivity for dBCT alone was 81.78%, 87.93% for dBCT plus SM, and 84.07% for DxM. dBCT plus SM had significantly higher sensitivity than DxM (p=0.0081), and dBCT alone (p<0.0001). DxM and dBCT alone did not differ in sensitivity (p=0.1753). The specificity for dBCT alone was 49.67%, 39.65% for dBCT plus SM, and 44.84% for DxM. Neither dBCT alone (p=0.1148) nor dBCT plus SM (p=0.0745) statistically differed from DxM. dBCT alone had a significantly higher specificity than dBCT plus SM (p<0.0001). The AUC based on BIRADS (POM) were 0.716 (0.770) for dBCT, 0.723 (0.791) for dBCT plus SM, and 0.724 (0.792) for DxM. There were no statistically significant differences between the modalities based on POM (p=0.3311) or BIRADS (p=0.8569) score analyses.

CONCLUSION

The most effective use of dBCT for diagnostic imaging is as adjunct to standard view mammography.

CLINICAL RELEVANCE/APPLICATION

Dedicated Breast Computed Tomography has potential for use as a diagnostic breast imaging tool.
**PURPOSE**

To investigate the feasibility of simultaneous conventional dynamic MR urography (MRU) and high temporal resolution perfusion MRI of bladder tumors using a novel free-breathing golden-angle radial acquisition scheme with compressed sensing reconstruction.

**METHOD AND MATERIALS**

22 patients with bladder lesions underwent MRU using the GRASP (Golden-angle RAdial Sparse Parallel) technique. Following contrast injection, GRASP was performed of the abdomen and pelvis during free breathing (voxel size 1.4x1.4x3.0 mm, 1,000 radial spokes, acquisition time 3:44 min). Two dynamic data-sets were retrospectively reconstructed from this single acquisition by combining a distinct number of spokes into each dynamic frame: 110 spokes per frame to provide a resolution of approximately 30 seconds, serving as conventional MRU for clinical interpretation, and 8 spokes per frame to provide 2 second resolution images for quantitative perfusion. Using the 2 second resolution images, ROIs were placed within the bladder lesion and normal bladder wall for all patients, an arterial input function was generated from the femoral artery, and the GKM perfusion model was applied.

**RESULTS**

Follow-up cystoscopy and biopsy demonstrated 16 bladder tumors (13 stage≥T2, 3 stage≤T1) and 6 benign lesions. All lesions were well visualized using the conventional 25 second clinical dynamic images. Based on the 2 second resolution images, Ktrans was significantly higher in bladder tumors (0.38±0.24) than in either normal bladder wall (0.12±8, p<0.001) or in benign bladder lesions (0.15±0.03, p=0.033). The ratio between Ktrans of the lesion and of normal bladder wall in each patient was nearly double in tumors than in benign lesions (4.34±3.4 vs. 2.2±1.6), and Ktrans was nearly double in stage≥T2 tumors than in stage≤T1 tumors (0.44±0.24 vs. 0.24±0.24), although these did not approach significance (p=0.180-0.209), likely related to small sample size.

**CONCLUSION**

GRASP DCE-MRI provides simultaneous conventional dynamic MR urography and high temporal resolution perfusion MRI of bladder tumors. Quantitative evaluation of bladder lesions based on the 2 second temporal resolution reconstructions showed associations with pathologic findings in our preliminary cohort.

**CLINICAL RELEVANCE/APPLICATION**

The novel GRASP sequence allows quantitative perfusion evaluation of bladder lesions within the context of a clinical MRU examination using a single contrast injection and without additional scan time.

PURPOSE
To evaluate contrast enhanced US (CEUS) for renal mass characterization in chronic renal insufficiency (CRI), comparing nondestructive (low MI) and destruction-reperfusion techniques.

METHOD AND MATERIALS
Prospective study comparing 48 subjects: 24 with normal function and renal masses scheduled for excision; 24 with CRI and indeterminate renal lesions on non-contrast US/CT. CEUS was performed on an Acuson Sequoia with CPS software. Perflutren (Definity) 1.3ml was given. Lesions were imaged at a low MI of 0.2. A 3 minute videoclip was recorded. Time Intensity curves (TICs) of the lesion and adjacent parenchyma were generated. A second dose of Definity was given and a Destruction Reperfusion (DR) sequence was performed on the same lesion. DR was performed under an IND exemption from the FDA. Bubble destruction was performed at an MI of 0.9. Reperfusion images were obtained using Motion Stabilized Persistence software (Siemens). A color-coded parametric map quantifying arrival time was generated in which Green=faster arrival, Red=slower, Black=no contrast. Reference standard was pathology, contrast CT/MR or absence of change on follow up imaging for benign lesions. Two blinded readers reviewed the low MI images and classified the lesions using Bosniak criteria.

RESULTS
Lesion size ranged from 1.7-7.6cm (mean 3.5cm). Histopathology of resected masses showed no cavitation or cellular injury from high MI of DR. DR arrival times correlated with low MI TIC parameters. Sensitivity for distinguishing Bosniak I/II/III from IIV was: Reader 1-96%, Reader 2-100%. Specificity was 78% and 63%. Specificity is lower because CEUS detects smaller lesions. DR arrival times correlated with low MI TIC parameters. Sensitivity for distinguishing Bosniak I/II/III from IV was 0.978, 0.982, 0.801, respectively. The combination of T2 and ADC produced the most complete separation between cancer and normal tissues, resulting in AUC of 0.995.

CONCLUSION
MR-F-PISP is a novel relaxometry sequence that allows quantitative examination of prostate in a clinical setting. The T1 and T2 relaxation times so obtained, in combination with ADC values show promising results in detecting prostate cancer.

CLINICAL RELEVANCE/APPLICATION
Quantitative MR parameters can help identify prostate cancer non-invasively. This could have broad applications in diagnosis, guiding biopsy, and following treatment.

SSA09-04 ARFI Evaluation of Small (<4 cm) Renal Masses. A Preliminary Study

Sunday, Nov. 29 11:15AM - 11:25AM Location: E351

To describe initial experience in detecting prostate cancer (PCA) using quantitative MRI parameters - T1 and T2 relaxation times derived from magnetic resonance fingerprinting (MRF-FISP), in combination with conventional ADC maps.

METHOD AND MATERIALS

63 patients with clinical suspicion of prostate cancer were imaged on 3T Siemens Skyra /Verio scanners. MRF has been shown to measure T1 and T2 relaxation times with high accuracy and precision. In addition to the standard multiparametric MRI exam, MRF-FISP was acquired (slice thickness: 6 mm, in-plane resolution: 1x1 mm2, FOV: 400 mm, TR: 11-13 ms, flip angle: 5-75 deg, duration: 50s per slice). b-values for DWI were 0, 500, 1000 s/mm2. T1, T2 maps were generated from MRF-FISP data and regions of interest (ROIs) were drawn on T1, T2 and ADC maps in areas suspicious for cancer identified based on PI-RADS score, and normal peripheral zone (NPZ). Matched pairs t-tests were used to compare T1, T2, ADC values in biopsy proven PCA and NPZ. Logistic regression model was applied to these parameters in differentiating PCa from NPZ. Receiver operating characteristic (ROC) analysis was performed for the parameters singly and in combination and area under the curve (AUC) was calculated.

RESULTS

29 patients were diagnosed with cancer on transrectal biopsy. T1, T2, ADC values were significantly lower in cancer compared to NPZ (p<0.0001). Mean T1, T2, ADC for prostate cancer were 1413±60ms, 66±3ms, 745±54 x 10^-6 mm2/s, respectively. For NPZ, these values were 2059±477ms, 165±8ms, 1736±37 x 10^-6 mm2/s. The AUC for T1, T2, ADC values in separating PCA from NPZ was 0.978, 0.982, 0.801, respectively. The combination of T2 and ADC produced the most complete separation between cancer and normal tissues, resulting in AUC of 0.995.

CONCLUSION

MR-F-PISP is a novel relaxometry sequence that allows quantitative examination of prostate in a clinical setting. The T1 and T2 relaxation times so obtained, in combination with ADC values show promising results in detecting prostate cancer.

CLINICAL RELEVANCE/APPLICATION

Quantitative MR parameters can help identify prostate cancer non-invasively. This could have broad applications in diagnosis, guiding biopsy, and following treatment.
**PURPOSE**
To evaluate if ARFI can be a reliable technique in distinguishing ccRCCs from other solid and fluid-containing small renal masses.

**METHOD AND MATERIALS**
31 small (<4 cm) renal masses (27 were solid - 17/27 ccRCCs, 2/27 chromophobe RCCs, 4 oncocytes and 1 angiomylipoma - and 4 were cysts) were prospectively evaluated using US and ARFI. Each lesion was assigned an ARFI value obtained from the average of 12 measurements. All the solid masses underwent resection; all the cystic lesions were Bosniak 2, so were evaluated with follow-up. The difference existing between the two groups was evaluated by means of Student’s t test. A cut off value was determined to distinguish between ccRCCs and other lesions and sensitivity, specificity, PPV, NPV and accuracy were determined.

**RESULTS**
ccRCCs are characterized by an higher ARFI value and - when compared with all the other lesions - the difference existing between the two groups was statistically significant (p<0.001). Considering a cut off value of 1.95 m/sec sensitivity, specificity, PPV, NPV and accuracy were respectively 94.1%, 78.6%, 84.2%, 91.7% and 87.1%.

**CONCLUSION**
ccRCC is characterized by an higher ARFI value which can be used to distinguish it from other solid and fluid containing masses.

**CLINICAL RELEVANCE/APPLICATION**
ARFI can be an useful tool in the evaluation of small renal masses, helping distinguish ccRCCs from other lesions.
PURPOSE
To evaluate image quality of kidney parenchyma in a spectrum of CT monoenergy levels and to select the optimal Monoenergy levels for visualization.

METHOD AND MATERIALS
IRB approval was obtained. 30-corticomedullary phase, IV contrast-enhanced CT abdomen scans (18 males, 12 females, mean age of 50 years) were evaluated. In each scan, kidney parenchyma (60 regions) was assessed. The scans were obtained from a 64-slice spectral detector CT prototype (Philips Healthcare, Cleveland, OH, USA) at 120 kVp with an average of 150 mAs. For each scan, simultaneous conventional polyenergetic and monoenergetic image datasets at 50, 60, 70, 100, and 140 keV were reconstructed. Two experienced radiologists analyzed subjectively in consensus visualization of the kidney parenchyma and selected the optimal visualization dataset based on the conspicuity of the cortex and medulla and compared to the conventional images. Objective kidney signal-to-noise ratio (SNR) in the optimal monoenergy images was measured and compared to data from the conventional CT images.

RESULTS
Optimal image quality for kidney visualization was subjectively selected with 60 - 70 keV monoenergy images and was judged to be better than the conventional dataset. The kidney SNR values in optimal monoenergy were highly significantly different (p<0.01) from conventional CT images. Average SNR was 10.9 and 16.3 in the conventional and optimal monoenergy respectively.

CONCLUSION
Optimal visualization of the kidney parenchyma on dual energy CT images is achieved with monoenergy image reconstruction at 60 - 70 keV based on both subjective and objective assessments and seems to improve image quality compared to conventional images.

CLINICAL RELEVANCE/APPLICATION
Optimal image quality in monoenergy images may be supplemental to conventional polyenergetic images and potentially increase the diagnostic yield.

PURPOSE
Virtual touch tissue imaging quantification (VTIQ) is a newly developed technique for the sonographic quantification of tissue elasticity. It has been used in the assessment of breast lesions. The purpose of this study was to determine the diagnostic performance of VTIQ in unclear testicular lesions.

METHOD AND MATERIALS
Twenty patients with known testicular pathology underwent conventional B-mode sonography with additional VTIQ of the testicular lesions using a Siemens Acuson S2000™ and S3000™ (Siemens Medical Solutions, Mountain View, CA, USA) system. Tissue mechanical properties were interpreted and compared in the VTIQ examination. The pathologic diagnosis was established after surgery or in the follow up examination in highly suspicious of benign lesions.

RESULTS
Over 36 months, 22 focal testicular lesions (median lesion size, 18 mm; range, 4-36 mm in 20 patients (median age, 43 years; range, 22-81 years) were examined. Lesions were hyperechoic (n = 1), hypoechoic (n = 14), isoechoic (n = 1), mixed echogenicity (n = 3) or anechoic (n = 3). Histological examination showed one benign lesion (6.25 %) with a mean size of 7 mm and 15 malignant lesions (93.75 %) with a mean size of 20 mm. The value of the shear wave velocity in normal testis tissue showed a mean shear wave velocity of 1.17 m/s. No value of the shear wave velocity could the measured in cystic lesions. The rest of the benign lesions showed a mean shear wave velocity of 2.37 m/s. The value of the shear wave velocity in germ cell tumours showed a mean shear wave velocity of 1.94 m/s and for seminoma it showed a mean shear wave velocity of 2.42 m/s.

CONCLUSION
VTIQ is a reliable new method for measuring qualitative and quantitative stiffness of testis lesions and tissue. The qualitative shear-
RESULTS were estimated and compared using ROC curve analysis. Sensitivity and specificity in tumor detection and characterization. The two imaging modalities were compared with cystoscopy and surgical results (N=8 patients) in order to assess the baseline US, and 4D Ultrasound with fly through (US virtual navigation system) by an expert radiologist blinded to cystoscopy.

METHOD AND MATERIALS

30 consecutive patients with previous detected urinary bladder lesions at cystoscopy were prospectively evaluated with 2D baseline US, and 4D Ultrasound with fly through (US virtual navigation system) by an expert radiologist blinded to cystoscopy results. The two imaging modalities were compared with cystoscopy and surgical results (N=8 patients) in order to assess the sensitivity and specificity in tumor detection and characterization. The diagnostic performance of 2D features and 4D ultrasound were estimated and compared using ROC curve analysis.

RESULTS

24/33 and 31/33 urinary bladder lesions were detected by 2 D US and 4 D Ultrasound respectively. The latter was also able to
identify two additional lesions not previously detected at traditional cystoscopy. The US features of the lesions were consistent with the one provided at cystoscopy with not significant differences in term of characterization.

Conclusion: Our preliminary results shows that 4 D ultrasound cystoscopy with fly through is more accurate than baseline 2D ultrasound to detect and characterize urinary bladder lesions with results comparable with traditional cystoscopy.

CONCLUSION

Our preliminary results shows that 4 D ultrasound cystoscopy with fly through is more accurate than baseline 2D ultrasound to detect and characterize urinary bladder lesions with results comparable with traditional cystoscopy.

CLINICAL RELEVANCE/APPLICATION

New ultrasound software such as 4 D ultrasound cystoscopy with fly through may help us to follow-up patients treated conservatively for urinary bladder lesions.

Sub-Events
SSA24-01 Percutaneous Biliary Drainage Catheters Fluid Dynamics: In Vitro Flow Rates and Patterns

PURPOSE
The purpose of our study was to evaluate the flow rates and patterns of simulated bile through drainage catheters in an in vitro biliary system model.

METHOD AND MATERIALS
The in vitro model consisted of a manometer-monitored constant pressure chamber containing simulated bile connected to a biliary tree made from airline and heat shrink cable tubing. Three types of 12-French drainage catheters (Cook Medical, Bloomington, IN) were inserted through a "T"-shaped sidearm in the biliary tree section of the model: biliary (32 sideholes along the shaft and locking pigtail), pigtail (6 sideholes within the pigtail), and a prototype pigtail catheter with a single sidehole in the catheter mid-shaft. Simulated bile at 4 different viscosities (guar gum solutions in water determined by a rotational viscometer to be in the range of human bile viscosity) flowed through the system under a constant pressure of 12 cm of water. A circumferential occlusion device was used to occlude distal flow. Flow volumes through each catheter were recorded over 1-minute intervals with the "common bile duct" unobstructed or obstructed. Ten trials were performed for each catheter and flow rates compared using Student’s t-test.

RESULTS
Without obstruction, there was no significant difference in the flow rates between all catheters tested. With obstruction, there was no significant difference in the flow rates between the prototype and standard biliary catheters while no flow was observed with the pigtail catheter. Fluid was seen flowing along the external shaft of all unobstructed catheters. In the obstructed prototype and biliary catheters, fluid was seen to exit from the sidehole(s) proximal to the obstruction and out of the distal sideholes.

CONCLUSION
Our data suggest that biliary drainage may be achieved with fewer sideholes proximal to the obstruction. Similar flow rates were obtained with multiple sideholes as compared to one proximal sidehole.

CLINICAL RELEVANCE/APPLICATION
Biliary catheters with multiple sideholes do not improve flow rates and may facilitate encrustation with debris that could lead to catheter obstruction and sepsis. Catheters with one or fewer sideholes may achieve the same flow rate while reducing the likelihood of catheter obstruction.
PURPOSE

to assess the mid-term outcome of biodegradable biliary stents (BBS) to treat benign biliary strictures.

METHOD AND MATERIALS

Institutional Review Board approval was obtained and patients' consent was waived. Between 2007 and 2014, ninety-nine patients (mean age 57±16 years [mean±standard deviation]), 57 males (61±15 years), 42 females (54±17 years), were treated. Technical feasibility, technical success, and immediate complications were recorded. In 89 patients (51 males, 38 females, aged 57±17 years) with at least 6 months follow-up (mean follow-up 20.2±19.9 months), late complications, episodes of cholangitis, episodes of altered hepatic functional tests without symptoms of cholangitis, episodes of biliary stones, and development of imaging demonstrated biliary stricture recurrence were recorded. Fisher's exact test, Mann-Whitney U test, and Cox regression model were used.

RESULTS

Stent implantation was feasible in 99/99 cases (100%). In 2/99 cases (2%), migration of the stent occurred immediately after deployment (technical success 98%). In 4/99 cases (4%), immediate mild haemobilia occurred. No major or late complications occurred. In 24/89 patients (26.9%) subsequent cholangitis occurred. 15/89 (16.8%) patients had episodes of altered hepatic functional tests without symptoms of cholangitis. Six out of 89 patients (6.7%) developed biliary stones. In 19/89 patients (21.3%), stricture recurrence occurred. The estimated mean time to stricture recurrence was 32.9 months (95% CI 29.6-36.2 months).

CONCLUSION

Percutaneous placement of BBS is a feasible, safe and effective strategy to treat benign biliary strictures and may represent a further option for treating patients in whom standard percutaneous therapy failed.

CLINICAL RELEVANCE/APPLICATION

Percutaneous placement of BBS is a feasible, safe and effective strategy to treat benign biliary strictures, potentially representing a further option for treating patients in whom standard percutaneous therapy failed.

Interventional MRI-Guided Local Delivery of Agents into Swine Bile Duct Walls Using MR Compatible Needle-Integrated Balloon Catheter System

Sunday, Nov. 29 11:05AM - 11:15AM Location: E352

Participants

Xiaoming Yang, MD, PhD, Seattle, WA (Abstract Co-Author) Nothing to Disclose

PURPOSE

To investigate the feasibility of interventional magnetic resonance imaging (MRI)-guided local agent delivery into pig common bile duct (CBD) walls using a newly-designed MR-compatible, needle-integrated balloon catheter system.

METHOD AND MATERIALS

We first designed a needle-integrated balloon catheter system that is comprised of a 22-G MR-compatible Chiba biopsy needle and a conventional 12mm×2cm balloon catheter. Under fluoroscopy guidance, a custom needle/balloon system was positioned into the target CBD via a transcholecystic access. T1-weighted MR imaging was used to localize and reposition the needle/balloon system in the target. A 0.5-mL mixture of motexafin gadolinium (MGd) and trypan blue dye as well as 5-fluorouracil (5-Fu) was delivered into the CBD wall through the needle/balloon system. Post-infusion T1-weighted MR imaging was obtained and contrast-to-noise ratios (CNR) of CBD walls of pre- and post-MGd/blue infusions were compared by a paired t-test. In addition, post-infusion x-ray cholangiography was achieved to evaluate the potential injuries of CBDs by the needle/balloon system. High-pressure liquid chromatography was used to quantify 5-FU in the bile duct tissue. Subsequent histologic analysis was performed to correlate and confirm the imaging findings.

RESULTS

Post-infusion cholangiogram didn't show any extravasation of contrast agent, indicating no procedure-related damage to the CBDs. MR imaging demonstrated the clear enhancement of the target bile duct walls infused with MGd/trypan blue dye with average penetration depth of 4.7±1.2mm. The average CNR of the post-infusion bile ducts was significantly higher than that of the pre-infusion bile ducts (110.6±22 vs 5.7±2.8, p<0.0001). Out of the total 5mg 5-Fu injected into the bile duct tissue, 4.1±0.12 mg 5-FU were retrieved, proving an approximately 80% drug delivery efficiency. Histology depicted the blue dye staining and red fluorescence of MGd through the target CBD walls, which was well correlated with the imaging findings.

CONCLUSION

It is feasible to use the new MR compatible, needle-integrated balloon catheter system for intrabiliary local agent delivery into CBD walls under MR imaging guidance.

CLINICAL RELEVANCE/APPLICATION

This study may open new avenues for efficient management of pancreatobiliary malignancies using MR-guided interventional oncology.
Liver failure represents the most severe post-operative complication of major hepatic resection. Our aim was to prospectively compare percutaneous portal vein embolization (PVE), portal vein ligation (PVL), and associating liver partition and portal vein ligation for staged hepatectomy (ALPPS) in terms of FLR hypertrophy, complications and clinical outcome.

METHOD AND MATERIALS
From January 2004 to January 2015, 118 patients with an inadequate FLR underwent procedures to induce preoperative hypertrophy before major liver resection. 73 patients underwent PVE, 27 underwent PVL and 18 ALPPS. PVE was percutaneously performed under US and fluoroscopy, with a 4-F catheter, using PVA particles, coils and glue. Total liver volume (TLV), tumor volume and FLR were calculated before both the procedure and surgery. The following outcome measures were considered: operating time, intraoperative blood losses, hospital stay, morbidity and mortality rate. Plasma samples were collected preoperatively and in 1st, 2nd and 5th postoperative day to assess liver function. Moreover, serum levels of white blood cells, C-reactive protein (CRP), Interleukin-6 (IL-6) and Endothelin-1 (ET-1) were determined as markers of inflammatory surgical stress response.

RESULTS
The three groups were homogeneous in terms of pre-procedural volumes, comorbidities and histopathological findings. In ALPPS group, FLR mean hypertrophy was higher than PVE and PVL groups (PVE=5.45 ± 3.17 cc/day, PVL=5.59 ± 2.19 cc/day, ALPPS =21.03 ± 11.09 cc/day, p<0.05). A higher grade of severe complications was recorded in ALPPS group compared to PVE and PVL groups. Postoperative plasma levels of AST, ALT, WBC, CRP, IL-6 and ET-1 showed a higher increase after the first surgical stage in the ALPPS series compared with the same stage of patients subjected to PVE/PVL.

CONCLUSION
PVE and PVL are comparable in inducing FLR hypertrophy. ALPPS assures the possibility to obtain a higher rate of hypertrophy in a shorter time even if with an higher rate of complications. PVE is preferable to PVL in all cases of unrerequired two stage hepatectomy. ALPPS should not be considered a substitute for PVE or PVL but rather a technique to expand the pool of resectable cases.
CLINICAL RELEVANCE/APPLICATION

Percutaneous PVE remains the first option to induce hypertrophy of the FLR in case of major hepatic resection. ALPPS should be proposed with caution in selected cases due to its high risk of complications.

SSA24-06 Root Cause Analysis of Rebleeding Events Following Transjugular Intrahepatic Portosystemic Shunt Creation for Variceal Hemorrhage

Sunday, Nov. 29 11:35AM - 11:45AM Location: E352

Participants
Janesh Lakho, BS, Chicago, IL (Presenter) Nothing to Disclose
James T. Bul, MD, Chicago, IL (Abstract Co-Author) Nothing to Disclose
Charles E. Ray Jr, MD, PhD, Chicago, IL (Abstract Co-Author) Advisory Board, Novate Medical Ltd; Editor, Thieme Medical Publishers, Inc
Grace Knuttinen, Chicago, IL (Abstract Co-Author) Nothing to Disclose
Ryan C. Gaba, MD, Chicago, IL (Abstract Co-Author) Nothing to Disclose

PURPOSE
To identify fundamental causes underlying recurrent variceal hemorrhage (VH) following transjugular intrahepatic portosystemic shunt (TIPS) creation in order to ascertain opportunities for improvement of TIPS-based management of VH and rebleeding prevention.

METHOD AND MATERIALS
In this single-center retrospective study, 166 patients (M:F=101:65, median age 52 years, median MELD score 14) who underwent TIPS creation for VH between 1999-2014 were studied. Medical record review was used to detect patients who had recurrent VH events, and root cause analysis (RCA) allowed identification of most probable causal factors. A 5-person Interventional Radiology physician group then generated quality improvement (QI) recommendations for process changes to address causal factors, with consensus achieved using a modified Delphi method.

RESULTS
Twenty-five (15%) patients suffered variceal rebleeding post-TIPS. The 1-, 3-, and 5-year variceal rebleeding incidence was 17%, 21%, and 21%. Variceal rebleeding was associated with high 90-day all-cause mortality incidence (10/25, 40%). Male gender (P=0.018) and MELD score (P=0.009) were statistically associated with variceal rebleeding. The most common primary and secondary causes of recurrent VH were lack of or insufficient variceal embolization (48%, 12/25) and coagulopathy (44%, 11/25). Other causal factors included TIPS stenosis or occlusion (n=8) with recurrent portosystemic pressure gradient (PSG) elevation (n=5), inadequate PSG reduction (n=3), and TIPS under dilation (n=1). Fourteen preventative QI recommendations, spanning items related to TIPS portal venous puncture, venographic assessment, stent type and deployment technique, PSG reduction, embolotherapy methodology, and coagulopathy correction, were developed to potentially address variceal rebleeding.

CONCLUSION
While recurrent VH rates following TIPS are non-trivial, rebleeding may be related to addressable underlying causal factors. Further investigation may assess the efficacy of QI-based procedure methodological enhancements in reducing post-TIPS rebleeding incidence.

CLINICAL RELEVANCE/APPLICATION

Root cause analysis based identification of fundamental reasons underlying recurrent variceal hemorrhage after TIPS creation may help reduce the significant morbidity and mortality associated with this condition by targeting causal factors for correction through quality improvement measures.

SSA24-07 Hemodynamic Effects of a Combined Therapy Using Partial Splenic Embolization and Transjugular Intrahepatic Portosystemic Shunt in Patients with Portal Hypertension and Hypersplenism

Sunday, Nov. 29 11:45AM - 11:55AM Location: E352

Participants
Amaud Geffray, Tours, France (Presenter) Nothing to Disclose
Julien Pucheux, MD, La Riche, France (Abstract Co-Author) Nothing to Disclose
Daniel Alison, MD, Tours, France (Abstract Co-Author) Nothing to Disclose
Jean-Marc Perarnau, MD, Tours, France (Abstract Co-Author) Consultant, W. L. Gore & Associates, Inc

PURPOSE
Portal hypertension (PHT) is the result of increased hepatic resistance and portal blood flow. Transjugular Intrahepatic Portosystemic Shunt (TIPS) treats PHT by decreasing portal resistance but it increases the portal blood flow and promotes hepatic encephalopathy and right heart failure. Partial splenic embolization (PSE) treats hypersplenism and could decrease the splenic blood flow before the TIPS placement. The purpose of this study was to investigate the portal hemodynamic effects of a concomitant procedure using PSE before the TIPS placement in patients with PHT and hypersplenism.

METHOD AND MATERIALS
Thirteen patients with PHT and hypersplenism underwent PSE and TIPS in a concomitant procedure. PSE, performed just before the TIPS placement, consisted in injecting non-selectively 1 or 2 vials of microspheres (900-1200μm) in the splenic artery. The portal pressure gradient (PPG) was assessed before and after PSE. TIPS procedure consisted in a Viatorr® stent (Gore) placement calibrated from 6 to 10 mm, in order to obtain a PPG lower than 12 mmHg.

RESULTS
PSE was performed for an indication of surgery (n=3), HCV interferon therapy (n=1), chemotherapy (n=1), high risk of haemorrhage...
PSE was performed for an indication of surgery (n=3), HCV interferon therapy (n=1), chemotherapy (n=1), high risk of hemorrhage because of severe thrombocytopenia, pancytopenia or recurrent bleeding from other sites than varices (n=5) and thrombocytopenia associated with hepatic encephalopathy (n=3). TIPS was carried out for the secondary prevention of variceal bleeding (n=6), refractory ascites (n=6) and portal venous thrombosis (n=1). The PPG decreased from 15.2 \pm 3.7 \text{mmHg} before PSE to 11.8 \pm 4.0 \text{mmHg} after PSE. This allowed limiting the TIPS size to 6 mm in 7 patients. The PPG was 6.3 \pm 2.1 \text{mmHg} after the TIPS placement. The platelet count increased from 52 \pm 27 \text{G/L} before PSE to 209 \pm 109 \text{G/L} two months after the combined therapy. After the procedure, there was one splenic abscess leading to death, one splenic hematoma and one hepatic abscess and three cases of transient hepatic encephalopathy.

CONCLUSION

Our study evaluated the hemodynamic effects of this combined therapy. It showed that PSE decreases the PPG and can allow the creation of a smaller caliber TIPS.

CLINICAL RELEVANCE/APPLICATION

Randomized controlled studies are needed to evaluate the possible benefits of this combined therapy over encephalopathy and complications of splanchic hemodynamic stress in patients with PHT and hypersplenism undergoing TIPS placement.

SSA24-08 The Effect of Locoregional Therapies and Transjugular Intrahepatic Portosystemic Shunting for Hepatocellular Carcinoma (HCC) Liver Transplant Patients: A UNOS Population Study

Sunday, Nov. 29 11:55AM - 12:05PM Location: E352

Participants

Minzhi Xing, MD, New Haven, CT (Presenter) Nothing to Disclose
Hyun S. Kim, MD, Atlanta, GA (Abstract Co-Author) Nothing to Disclose

PURPOSE

To investigate the utility of bridging locoregional therapies (LRT) and transjugular intrahepatic portosystemic shunts (TIPS) in HCC patients undergoing orthotopic liver transplant (OLT) and its effect on survival outcomes in a national population study.

METHOD AND MATERIALS

The United Network for Organ Sharing (UNOS) database was used to identify patients who were listed for OLT from 2002 to 2013 and followed through 2014. Patients within the Milan Criteria with approved HCC Model for End-Stage Liver Disease (MELD) exception and available pre-OLT TIPS placement data were included. Overall survival (OS) from OLT was stratified by TIPS status and bridging LRT (including transarterial chemoembolization (TACE), radiofrequency ablation (RFA) and cryoablation). Chi-squared tests were used to compare categorical variables and t-tests to compare continuous variables. Kaplan-Meier estimation and log-rank test were used for survival analysis.

RESULTS

Of 17,291 HCC patients who were listed for OLT during the study period, 14,511 patients received OLT, of whom 13,299 patients had adequate pre-OLT TIPS placement data, mean age 57.5 years, 77.1% male; 616 (4.6%) patients received pre-OLT TIPS, and 6,358 patients received at least one LRT. Comparison groups were similar for age at OLT, waitlist duration, gender, ethnicity, BMI, Child and MELD scores (p>0.05 for all). No significant differences in survival from OLT were observed between patients who received pre-OLT TIPS (mean 108.6 months) vs. those who did not (118.9 months), p=0.84. TIPS Patients who received at least one bridging LRT had significantly higher mean survival vs. those who received no bridging LRT (106.1 vs. 102.5 months, p=0.03).

CONCLUSION

In a national population study, OS from transplant in HCC patients was not significantly affected by pre-OLT TIPS placement status. TIPS Patients who received at least one bridging locoregional therapy had significantly improved post-OLT survival compared to those who did not.

CLINICAL RELEVANCE/APPLICATION

Pre-OLT TIPS for HCC patients may be safely performed without significant impact on post-OLT survival. Bridging LRT may improve post-OLT survival in HCC patients who require TIPS placement.
pre-OLT TIPS placement data, mean age 48.9 years, 67.4% male; 5,304 (7.6%) patients received pre-OLT TIPS. Comparison groups were similar for age at OLT, waitlist duration, gender, ethnicity, BMI, Child and MELD scores (p>0.05 for all). No significant differences in survival from OLT were observed between patients who received pre-OLT TIPS (mean 112.9 months) vs. those who did not (123.6 months), p=0.07. There were significant regional and geographic differences in TIPS placement rates (range 1.9-12.24%, p<0.001) and mean OS from OLT (range 36.3-101.9 months, p<0.001). Increasing longitudinal 12-month OS rates were observed in both TIPS and non-TIPS patients from 2002-2012.

CONCLUSION

In a national population study, OS from transplant was not significantly affected by pre-OLT TIPS placement status. Increasing longitudinal trends in 12-month post-OLT survival and significant geographic disparities in TIPS placement rates and survival from OLT were observed.

CLINICAL RELEVANCE/APPLICATION

Pre-OLT TIPS may be safely performed without significant impact on post-OLT survival.

Eun Sun Lee, MD, PhD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Joon Koo Han, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To evaluate the diagnostic performance of 18F-FDG PET/MRI in the assessment of local resectability, N staging, and M staging in patients with pancreatic cancer compared with 18F-FDG PET/CT plus contrast-enhanced MDCT.

**METHOD AND MATERIALS**

In this prospective study, a total of 37 patients with 39 pancreatic cancers were enrolled and underwent 18F-FDG PET/MRI, 18F-FDG PET/CT, and contrast-enhanced MDCT within 2 weeks of each other. Mean and maximum standardized uptake values (SUVs) in PET/MRI and PET/CT of pancreatic cancers were measured. Two independent radiologists retrospectively reviewed two imaging sets (set 1: PET/MRI, set 2: PET/CT plus MDCT) to evaluate tumor conspicuity and local resectability using a 5-point scale, and to determine preoperative N staging (N0 or N+) and M staging (M0 or M1). Diagnostic performances two imaging sets were compared using paired t-test, ROC analysis, and McNemar test.

**RESULTS**

Both mean and maximum SUVs of the pancreatic cancer showed strong correlations between PET/MRI and PET/CT (r=0.89 and 0.90, P<0.0001). Tumor conspicuity was slightly higher in PET/MRI set than PET/CT plus MDCT set (3.64 vs. 3.36, and 3.49 vs. 3.23 in reviewers 1 and 2, respectively; P>0.05). Diagnostic performance of PET/MRI in assessing local resectability was equivalent to PET/CT plus MDCT (Az values of 0.857 vs. 0.725, and 0.875 vs. 0.754 in reviewers 1 and 2, respectively; P>0.05). There were no statistically significant difference in the diagnostic accuracies for N- and M-staging between two imaging sets (N-staging: 52.6% vs. 42.1%, and 57.9% vs. 42.1%; M-staging: 75.0% vs. 79.2%, and 79.2% vs. 83.3%, in reviewers 1 and 2, respectively; P>0.05).

**CONCLUSION**

In this preliminary study in patients with pancreatic cancer, diagnostic performance of 18F-FDG PET/MRI is comparable to that of 18F-FDG PET/CT plus contrast-enhanced MDCT in the preoperative assessment of local resectability, N-staging, and M-staging.

**CLINICAL RELEVANCE/APPLICATION**

In the preoperative assessment of resectability and staging of pancreatic cancer, 18F-FDG PET/MRI, as an one-step whole-body imaging tool, may serve as an alternative to PET/CT plus MDCT.

Michael D. Kluger, MD, New York, NY (Abstract Co-Author) Nothing to Disclose
**PURPOSE**

To assess agreement between IVIM derived parameters and histopathology in participants with suspected pancreatic ductal adenocarcinoma (PDA) undergoing surgical resection.

**METHOD AND MATERIALS**

18 patients (9M:9F, mean 68y) were prospectively enrolled in this IRB approved, HIPAA compliant study with informed consent. All underwent respiratory-triggered axial EPI DWI with b-values from 0 to 800 within 1 month of surgery (mean, 6d). Two experienced radiologists (>10y each) independently drew 2 ROIs over tumor and surrounding non-tumoral tissue when present and individual results were averaged. Mono (ADC0-800, ADCtotal) and bi-exponential (true diffusion (D), "pseudo"- diffusion (D*) and perfusion fraction (f)) fitting were derived using open source MITK software (MITK.org). DWI metrics were compared with quantitative histopathology including % fibrosis, tumor cell density, and mean vascular density (MVD). Statistical analysis included intra-class correlation, Pearson correction and student t-test.

**RESULTS**

16 patients had PDA (Grade 2 (n=7), 2-3 (n=4), 3 (n=5),1 cholangi carcinoma and 1 metastatic renal cell carcinoma (mRCC). Non-tumoral pancreas tissue was available in 14/18 patients specimens. Mean reader ROI size for tumor and non-tumoral tissue was not significantly different (p>0.05). Reader agreement was moderate-high (0.68-0.98) for ADC, f and D. Histopathology revealed that MVD was significantly lower in tumor as compared to non tumor (p=0.002) and % fibrosis was significantly higher in tumor (p=0.004). D, f and ADC0-800 were not significantly different between tumor and non-tumor tissue for either reader. There was moderate but significant correlation between D and % fibrosis in tumor tissue (excluding mRCC) for each reader (Reader 1, r=-0.48, p=0.04; Reader 2, r=-0.59, p=0.01. Including non-tumor and tumor tissue significance was maintained (Reader 1, r=-0.43, p=0.02; Reader 2, r=-0.47, p=0.007). D was lower for grades 3-4 vs. grades 1-2 fibrosis (1.11 μm²/ms vs. 1.45 μm²/ms, p=0.05). MVD did not significantly correlate with f or fD*. Cell density/tumor grade did not correlate with IVIM metrics.

**CONCLUSION**

D negatively correlates with % fibrosis in tumor and non-tumoral pancreatic tissue and may serve as a biomarker of treatment response.

**CLINICAL RELEVANCE/APPLICATION**

Development of imaging biomarkers that can monitor desmoplasia in pancreatic adenocarcinoma would be clinically useful.
**SSA06-04** Enhancement Pattern of Pancreatic Neuroendocrine Tumors on Dynamic Enhanced CT: A Comparison between Tumors with Different Degree of Fibrosis Component

**Participants**
Cherry Kim, MD, Seoul, Korea, Republic Of (Presenter) Nothing to Disclose
Jae Ho Byun, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Seung-Mo Hong, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Jin Hee Kim, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Seung Soo Lee, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Hyong Jung Kim, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Moon-Gyu Lee, MD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
To compare the enhancement pattern and other CT findings between pancreatic neuroendocrine tumor (NET) with different degree of fibrosis component.

**METHOD AND MATERIALS**
We retrospectively reviewed the CT images of 45 patients (17 males and 28 females) with surgically confirmed NET containing fibrotic component > 30% of the whole tumor (Group A). They were matched for age, gender, and tumor grade at a ratio of 1:1 to 45 NET patients with fibrotic component < 30% (Group B). Hounsfield unit (HU) of tumors in the precontrast (PC), arterial (AP), and portal (PP) phases, HU ratio (tumor to normal parenchyma) in each phase, HU enhancement pattern (progressive enhancement or wash-out pattern), and visible enhancement pattern change from AP to PP (peripheral to full, peripheral to peripheral, full to peripheral, or full to full) were compared between Group A and B. Other CT findings, including heterogeneity of enhancement, calcification, margin, perilesional infiltration, pancreatic duct dilation, direct invasion, lymph node and distant metastasis, were also compared between the two groups.

**RESULTS**
Group A showed progressive enhancement pattern and Group B showed wash-out pattern (P<0.05). HU of tumors and HU ratio in PC were higher in group A than in group B (42.5±47.5 vs. 38.6±48.2; 1.02±0.28 vs. 0.88±0.23; P≤.024), whereas those in AP were lower in group A than in group B (146.2±48.2 vs. 183.1±49.7; 1.4±0.52 vs. 1.61±0.38; P≤.003). Peripheral to full or peripheral enhancement change was more frequent in group A, while full to full enhancement change was more frequent in Group B (P<0.05). Other CT findings were not significantly different between the two groups (P>.05).

**CONCLUSION**
On dynamic enhanced CT, NET with rich fibrotic component tended to show progressive enhancement pattern and peripheral to full or full enhancement change, while NET with poor fibrotic component tended to show wash-out pattern and full to full enhancement change.

**CLINICAL RELEVANCE/APPLICATION**
CT enhancement pattern has been suggested as a prognostic indicator of pancreatic NET. However, its degree of fibrotic component could be one of causes for its various enhancement patterns.

**SSA06-05** Using Iodine Quantification from DECT Images to Differentiate Pancreatic Neuroendocrine Tumors from Splenules

**Participants**
Andrea Prochowski Jamuri, MD, Boston, MA (Presenter) Nothing to Disclose
Manuel Patino, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose
Diana Murcia, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose

Dushyant V. Sahani, MD, Boston, MA (Abstract Co-Author) Research Grant, General Electric Company; Research Consultant, Allena Pharmaceuticals, Inc

**PURPOSE**
Differentiating intrapancreatic splenule from other solid pancreatic masses and pancreatic neuroendocrine tumors (pNET) can be challenging on a single phase CT exam. We investigated the role of iodine quantification from DECT for characterizing splenules (SPL).

**METHOD AND MATERIALS**
In this retrospective study, 45 patients (16 with pNET and 29 with SPL) underwent to portal phase DECT (750HD GE) and material decomposed iodine images (MD-I) were used to quantify mean iodine concentrations (MIC) for pNET, SPL, and aorta. Normalized iodine concentration (NIC) were calculated for pNET, SPL and spleen. MIC of pNET and of SPL were compared with spleen MIC. On the SECT images, mean HU (MHU) values were calculated for pNET, SPL, and spleen. NIC and MHU values of lesions and spleen and their ratio were compared using a t-test. Lesion appearance was evaluated on MD-I with a scale from 1 to 3 (1 homogenous, 2 mild heterogeneity, 3 heterogeneous).

**RESULTS**
NIC values were: pNET 0.73±0.2, SPL 0.66±0.1 and spleen 0.66±0.1. The MIC ratio between pNET and spleen was 1.14±0.3, and for SPL/spleen 1.01±0.1 (p=0.047). The MHU ratios between pNET and spleen was 0.92±0.2 and for SPL/spleen 0.86±0.1 (p=0.174). SPL also demonstrated a homogenous appearance (29) vs the heterogeneous appearance of pNET (16, 4=mild heterogeneity, 12=obvious heterogeneous).

**PURPOSE**
Differentiating intrapancreatic splenule from other solid pancreatic masses and pancreatic neuroendocrine tumors (pNET) can be challenging on a single phase CT exam. We investigated the role of iodine quantification from DECT for characterizing splenules (SPL).

**METHOD AND MATERIALS**
In this retrospective study, 45 patients (16 with pNET and 29 with SPL) underwent to portal phase DECT (750HD GE) and material decomposed iodine images (MD-I) were used to quantify mean iodine concentrations (MIC) for pNET, SPL, and aorta. Normalized iodine concentration (NIC) were calculated for pNET, SPL and spleen. MIC of pNET and of SPL were compared with spleen MIC. On the SECT images, mean HU (MHU) values were calculated for pNET, SPL, and spleen. NIC and MHU values of lesions and spleen and their ratio were compared using a t-test. Lesion appearance was evaluated on MD-I with a scale from 1 to 3 (1 homogenous, 2 mild heterogeneity, 3 heterogeneous).

**RESULTS**
NIC values were: pNET 0.73±0.2, SPL 0.66±0.1 and spleen 0.66±0.1. The MIC ratio between pNET and spleen was 1.14±0.3, and for SPL/spleen 1.01±0.1 (p=0.047). The MHU ratios between pNET and spleen was 0.92±0.2 and for SPL/spleen 0.86±0.1 (p=0.174). SPL also demonstrated a homogenous appearance (29) vs the heterogeneous appearance of pNET (16, 4=mild heterogeneity, 12=obvious heterogeneous).
CONCLUSION
On the MD-I images from DECT, SPL's are homogenous and follow the iodine concentration of spleen whereas pNET are often heterogenous and show higher NIC values than spleen.

CLINICAL RELEVANCE/APPLICATION
Inaccurate diagnosis of intrapancreatic SPL and pNET on portal phase CT often leads to unnecessary interventions and surgeries and occasionally delay in much needed surgery in the cases of pNET. Reliable diagnosis of splenule on portal-venous phase DECT is feasible by subjective assessment and iodine quantification.

PURPOSE
Previous studies suggest that enhancement patterns of pancreatic ductal adenocarcinoma (PDAC) reflect tumor angiogenesis and fibrosis, both of which are implicated in PDAC prognosis. The purpose of this study is to determine whether the degree of enhancement of resectable PDAC at pancreatic phase CT can predict subsequent early development of metastases.

METHOD AND MATERIALS
We retrospectively identified 38 patients with resectable PDAC who underwent multiphase pancreatic protocol CT prior to surgery (no neoadjuvant therapy), and who had >= 12 month follow up at our institution. Tumor enhancement was determined by measuring CT attenuation change (Δ Hounsfield unit (HU)) between the pancreatic phase and unenhanced images. Tumor grade, size, and AJCC stage at pathology were recorded. Follow up imaging studies were reviewed to determine any subsequent development of metastatic disease and its timing in these patients. Uni- and multi-variate analyses were used to determine predictors of the development of metastases within 12 month of surgery.

RESULTS
Fourteen of the 38 patients had developed metastases (liver, lung, peritoneum) by 12 months. The mean tumor enhancement in patients who had developed metastases by 12 months was significantly lower than that of patients who did not (32.1±13.7HU vs. 55.9±48.9HU, p=0.0002). A threshold of 40HU identified patients with metastases by 12 months with 79% sensitivity and 92% specificity. Both tumor grades and size at pathology were significantly higher in patients with metastases by 12 months than those without (both p values < 0.05). There was a trend of higher tumor stages in patients with metastases by 12 months (p=0.06). 32/38 patients underwent gemcitabine based adjuvant therapy post resection. The proportion of patients receiving adjuvant therapy was not significantly different between the two groups. Multivariate analysis showed that tumor enhancement < 40HU and tumor grade were independent predictors of development of metastases by 12 months (both p values <0.05).

CONCLUSION
Low contrast enhancement (<40HU) of primary PDAC is associated with development of metastases by 12 months following resection.

CLINICAL RELEVANCE/APPLICATION
Enhancement pattern of primary PDAC at CT may be a useful prognostic marker.
chemotherapy

METHOD AND MATERIALS
Twenty patients (13 males, 7 females, average age 67.8±11.8 years) with newly diagnosed pancreatic adenocarcinoma were scanned with dual source dual energy CT before and after (average interval: 71.9±42.8 days) chemotherapy. Dual phase CT protocol included arterial phase timed by bolus tracking, followed by a 60 second venous phase scanned with dual energy CT at 100 kV and 140 kV with tin filtration with reference dose of 250 and 193 mAs, respectively. Tumor segmentation was performed on a workstation using automated segmentation followed by manual editing. Iodine uptake by the tumor was obtained as an iodine concentration (mg/mL) and normalized by iodine uptake within the abdominal aorta (‘normalized tumor iodine uptake’). Tumor iodine uptake was compared to change in tumor volume and tumor markers.

RESULTS
At baseline, average iodine uptake by tumor was 1.26±0.37mg/mL in arterial phase and 1.79±0.50mg/mL in venous phase, and average normalized tumor iodine uptake was 0.10±0.05 in arterial phase and 0.38±0.09 in venous phase. After chemotherapy, average normalized tumor iodine uptake was significantly decreased compared to the baseline in both arterial phase (0.08±0.04 [p=0.016]) and venous phase (0.31±0.09 [p=0.007]). The tumor was decreased in volume in 17 patients (average volume change: 71±15%), and increased in 3 patients (average volume change: 154±22%). Average normalized iodine uptake in tumors that reduced volume greater than 20% after chemotherapy (n=9) was 72% and 77% of the baseline in arterial and venous phase respectively, lower than that of the other tumors (n=11) (88% of the baseline in both phase), but there was no statistically significantly difference. Average normalized tumor iodine uptake in patients with decreased tumor markers (n=8) were 74% and 80% of the baseline in arterial and venous phase, and in patients with increased tumor markers (n=3) were 116% and 96% of the baseline in arterial and venous phase, but the number of subjects were too small for statistical analysis.

CONCLUSION
Iodine uptake by pancreatic adenocarcinoma evaluated using dual energy CT may decrease after chemotherapy.

CLINICAL RELEVANCE/APPLICATION
Iodine uptake by pancreatic adenocarcinoma evaluated by dual energy CT may be potentially useful for assessment of treatment response.

SSA06-08 Agreement of Results of CT-perfusion Measurements in Pancreatic Carcinoma: Comparison of Three Different Kinetic Calculation Models
Sunday, Nov. 29 11:55AM - 12:05PM Location: E353A

Participants
Gerd Grozinger, MD, Tubingen, Germany (Presenter) Nothing to Disclose
Sven Schneeweis, Tubingen, Germany (Abstract Co-Author) Nothing to Disclose

Marius Horger, MD, Tuebingen, Germany (Abstract Co-Author) Nothing to Disclose

PURPOSE
To evaluate the interchangeability of perfusion parameters between three calculation methods for the post-processing of perfusion-CT images in pancreatic carcinoma.

METHOD AND MATERIALS
Perfusion-CT images was performed in 48 (32 male; mean age: 69.49 years) patients with adenocarcinoma of the pancreas. Images were post-processed using a software package based on the maximum-slope approach (blood flow-BF and blood volume-BV) and Patlak analysis (BV and k-trans), as well as a software package with deconvolution-based analysis (BF, BV and k-trans). Volume-of-interest (VOI) analysis of the tumor average perfusion was performed. Perfusion parameters were compared using the Wilcoxon matched-pairs test and Bland-Altman plots. Following CT-examinational protocol: 80kV, 100/120mAs, 64x0.6mm collimation, 26 consecutive scans, IV injection of 50 mL contrast at a flow rate of 5 mL/s, was used.

RESULTS
48 VOIs of tumors were analyzed. Moderate to good correlations were demonstrated between the various perfusion values (r = 0.42-0.90, P < .001). The Wilcoxon test revealed a significant difference between the methods (P < .001), with the BF and BV values obtained using the maximum-slope approach and Patlak analysis being lower than those obtained using deconvolution-based analysis. For analysis of k-trans deconvolution revealed significantly lower values (P<0.001). The Bland-Altman plots for BF and BV values revealed a proportionality trend with outliers, which were strongly associated with the magnitudes of the parameters. Analysis of the k-trans values did not show any systematic bias. Comparison of the three different BV-calculations revealed an equal distribution.

CONCLUSION
There were significant differences in the perfusion parameters obtained using the three software packages, and therefore these parameters are not directly interchangeable. However, the magnitude of pairs of parametric values is in constant relation to each other enabling the use of any of these methods.
Role of Sarcopenia and Visceral Obesity, Assessed Using Preoperative CT-scan, as Predictors of Short-term Outcome Following Pancreaticoduodenectomy in Pancreatic Cancer Patients

Sunday, Nov. 29 12:05PM - 12:15PM Location: E353A

CLINICAL RELEVANCE/APPLICATION

Perfusion-based tumor characterization could emerge as a more sensitive treatment monitoring and therefore cognizance of perfusion parameter values obtained with existing software packages is mandatory.

PURPOSE

Recent reports showed that body composition parameters, assessed using computed tomography (CT) images, may improve preoperative risk stratification in oncologic Patients. The aim of this study is to evaluate how sarcopenia (depleted muscle mass) and visceral obesity impact on postoperative outcome in pancreatic cancer patients treated with pancreaticoduodenectomy (PD) in a high volume Institution, focusing on mortality and pancreatic fistula (PF) occurrence.

METHOD AND MATERIALS

Between 2010 and 2014, 284 consecutive patients underwent PD for pancreatic cancer; among them 202 patients underwent preoperative staging CT-scan imaging at our Institution within 30-days before PD, and were included in this study. Total abdominal muscle area (TAMA), visceral fat area (VFA) and subcutaneous fat area (SFA) were assessed using Slice-O-Matic 5.0 software (Tomovision, Montreal, Canada); TAMA and VFA were evaluated on two contiguous slices at the third lumbar vertebra, and then averaged, using Hounsfield unit threshold of -29 to +150 for skeletal muscle, -150 to -50 for visceral adipose tissue and -190 to -30 for subcutaneous and intermuscular fat. Perioperative variables and postoperative outcomes were prospectively collected. Multivariate analysis was performed to identify independent predictors of 60-day mortality, and PF graded according to International Study Group of Pancreatic Fistula criteria. Sarcopenia was defined using predetermined sex-specific cut-off values (52.4 cm²/m² for men and 38.5 cm²/m² for women).

RESULTS

132 (65.4%) patients were classified as sarcopenic. Postoperative mortality occurred in 12 patients (5.9%), major complications in 40 (19.8%) and pancreatic fistula in 48 patients (23.8%). At multivariate analysis, VFA/TAMA and ASA score = 3 were the strongest predictors of mortality (p<0.001). Among patients who developed major complications, survivors had significantly lower VFA/TAMA ratio than non-survivors (p=0.017). VFA was an independent predictor of PF (p<0.001).

CONCLUSION

Preoperative analytic morphometric assessment, using CT images, is a useful tool for the prediction of mortality and pancreatic fistula occurrence, following PD for cancer.

CLINICAL RELEVANCE/APPLICATION

Preoperative CT assessment of sarcopenia and visceral adiposity improve risk stratification in patients undergoing pancreaticoduodenectomy for cancer, predicting mortality and pancreatic fistula occurrence.
LEARNING OBJECTIVES

1) To understand the role of computed tomography (CT) and positron emission tomography (PET)/CT in the management of patients with Hodgkin and non-Hodgkin lymphoma. 2) To review the new Lugano Classification:Recommendations for Initial Evaluation, Staging, and Response Assessment of Hodgkin and Non-Hodgkin Lymphoma. 3) To assess the limitations and potential of PET/CT and PET/MR in assessing lymphoma evaluation and treatment response.

ABSTRACT

FDG PET/CT and contrast-enhanced CT both play an important role in lymphoma, for initial evaluation, staging and assessing response to therapy. In this session we will review the current and evolving role of imaging in lymphoma and demonstrate how it guides therapy in this patient population. The limitations and future developments of PET imaging in the context of PET/CT and PET/MRI will be addressed and discussed.

**PURPOSE**

Differentiating osteoblastic metastases from benign enostoses on CT can be challenging. The purpose of our study was to determine if CT density thresholds of osteoblastic bone lesions can be used to distinguish untreated osteoblastic metastases from benign enostoses.

**METHOD AND MATERIALS**

Our study was IRB approved and complied with HIPAA guidelines. The study group comprised 62 patients (mean age 62± 20 y, 35 f, 27m) with sclerotic bone lesions found on CT. Etiology of sclerotic lesions was assessed by biopsy (n=17) or clinical and imaging follow-up (n=45). None of the patients had prior treatment for metastases. CT density of all lesions was measured by a MSK and an abdominal imaging fellow. If multiple lesions were present, the largest lesion was evaluated. The average and maximum densities in Hounsfield Units (HU) were measured. ROC analysis was performed to determine sensitivity and specificity, area under the ROC (AUC), and confidence intervals (CI), as well as cutoff values of CT densities to differentiate metastases from enostoses. Interreader reproducibility was assessed using intraclass correlation coefficient (ICC) with 95% CI.

**RESULTS**

A total of 37 enostoses and 25 untreated osteoblastic metastases were evaluated (primary tumors: breast cancer n=12, prostate cancer n=11, ovarian cancer n=1, transitional cell carcinoma n=1). Mean and maximum CT densities of enostoses were 1190 HU and 1323 HU, respectively and of osteoblastic metastases were 654 HU and 787 HU, respectively. Using a cut-off of 885 HU for average density, the AUC was 0.982, sensitivity was 94.6%, and specificity was 96%. Using a cut-off of 1058 HU for maximum CT density, the AUC was 0.976, the sensitivity was 94.6%, and specificity was 96%. ICC for mean density was 0.987 for enostoses and metastases. ICC for maximum density was 0.814 for enostoses and 0.980 for metastases.

**CONCLUSION**

Density measurements using CT can be used to distinguish untreated osteoblastic metastases from enostoses.

**CLINICAL RELEVANCE/APPLICATION**

An average density of 885 HU and a maximum density of 1058 HU provide reliable thresholds below which a metastatic lesion is the favored diagnosis.

**SSA14-04 Multiparametric Approach with Diffusion Weighted Imaging (DWI) and Dynamic Contrast Enhanced (DCE) Magnetic Resonance Imaging (MRI): A Comparison Study in Differentiation between Benign and Malignant Bone Lesions**

**Sunday, Nov. 29 11:15AM - 11:25AM Location: E451A**

**PURPOSE**

To evaluate and compare the diagnostic performance of quantitative parameters derived from DWI and DCE-MRI in differentiating...
METHOD AND MATERIALS
This study obtained IRB approved. Fifty five patients (23 men, 32 women; 21-82 years; mean age of 55 years) underwent MRI prior to treatment. ADC values were calculated by using three DW images (b = 0, 400, and 1400). DCE-MRI data were analyzed yielding estimates of Ktrans (volume transfer constant), Ve (extravascular extracellular volume fraction) and Kep (rate constant) with population based arterial input function. Additionally, a ratio of Ktrans and ADC was calculated. Difference of each parameter between benign and malignant bone tumors were evaluated after adjusting age and sex. ROC curve analysis was done to calculate and compare sensitivity, specificity, accuracy, positive predictive value, negative predictive value, and AUC after determining the optimal cut-off value for each parameter. Odds ratio (ORs) with 95% confidence intervals of each parameter in diagnosing malignant bone tumor was calculated with logistic regression.

RESULTS
Fifty five lesions were pathologically proven benign (n=19), and malignant (n=36) bone tumor. All parameters except Ve were significantly different between benign and malignant bone tumors. The highest AUC was seen in Ktrans, followed by Ktrans/ADC.

CONCLUSION
Quantitative parameters, Ktrans, Kep, ADC, and Ktrans/ADC, are good to differentiate benign and malignant bone tumor. Ktrans/ADC shows superior performance in differentiation of malignant and benign bone tumors, suggesting that the combination of parameters derived from perfusion and diffusion MRI may be much useful for differentiating benign and malignant bone tumor.

CLINICAL RELEVANCE/APPLICATION
Multiparametric approach for the differentiation of benign and malignant bone is feasible with DWI and DCE-MRI. A parameter combining both DWI and DCE-MRI may be much useful.

SSA14-05 Whole Body MRI Assessment of Bone Involvement in Prostate Cancer and Multiple Myeloma: Diagnostic Accuracy of Different Sequences

Sunday, Nov. 29 11:25AM - 11:35AM Location: E451A

PARTICIPANTS
Ahmed Larbi, MD, Nimes, France (Presenter) Nothing to Disclose
Patrick Omoun, MD, Lausanne, Switzerland (Abstract Co-Author) Nothing to Disclose
Vasiliki Pasogou, MD, Brussels, Belgium (Abstract Co-Author) Nothing to Disclose
Bertrand Tombal, Brussels, Belgium (Abstract Co-Author) Nothing to Disclose
Catherine Cyteval, MD, Montpellier, France (Abstract Co-Author) Nothing to Disclose
Frederic E. Lecouvet, MD, Brussels, Belgium (Abstract Co-Author) Nothing to Disclose

PURPOSE
To assess the diagnostic accuracy of the different sequences obtained in whole-body MRI (WB-MRI/DWI) in detecting bone involvement in patients with prostate cancer (PCa) and multiple myeloma (MM).

METHOD AND MATERIALS
Two musculoskeletal radiologists reviewed WB-MRI studies in 50 patients with PCa at high risk for metastasis and in 47 patients with suspicion of MM. WB-MRI examinations included anatomical coronal T1- and STIR-weighted sequences, and functional diffusion-weighted (DWI) sequences. The readers successively assessed individual sequences (T1, STIR, DWIBS), then pairs of sequences (T1/DWIBS, T1/STIR, STIR/DWIBS), and finally all sequences together (T1/STIR/DWIBS) to detect bone involvement. The gold standard was established on the basis of a panel review of all sequences.

RESULTS
Inter-observer agreement was good to excellent with similar kappa in both groups (.71 to .96). In the 'PCa' group, the study demonstrated the superiority of T1-weighted (Se 100%, Sp 92%) and DWI (Se 97%, Sp 92%) sequences, and of the pair T1/DWIBS (Se 100%, Sp 100%) for the detection of patients with bone involvement. Isolated reading of STIR sequences lacked accuracy (Se 91%, Sp 92%) for detecting bone metastases. In the 'MM' group, the study demonstrated the insufficiency of individual sequences (Se 83-93%, Sp 70%) to detect bone involvement. The best diagnostic accuracy was achieved by the combined reading of all sequences T1/STIR/DWIBS (Se 93%, Sp 88%).

CONCLUSION
To detect bone involvement, the combined reading of T1- and DWI-weighted sequences appears sufficient in PCa, whereas the combined reading of all sequences is necessary in MM.

SSA14-06 Correlation between Intravoxel Incoherent Motion Diffusion-weighted MR Imaging Parameters and Dynamic Contrast-enhanced MR Perfusion Parameters in Patients with Bone Metastasis from Non-Small Cell Lung Cancer at 3.0 T

Catherine Cyteval, MD, Montpellier, France (Abstract Co-Author) Nothing to Disclose
Frederic E. Lecouvet, MD, Brussels, Belgium (Abstract Co-Author) Nothing to Disclose

PURPOSE
To assess the diagnostic accuracy of the different sequences obtained in whole-body MRI (WB-MRI/DWI) in detecting bone involvement in patients with prostate cancer (PCa) and multiple myeloma (MM).

METHOD AND MATERIALS
Two musculoskeletal radiologists reviewed WB-MRI studies in 50 patients with PCa at high risk for metastasis and in 47 patients with suspicion of MM. WB-MRI examinations included anatomical coronal T1- and STIR-weighted sequences, and functional diffusion-weighted (DWI) sequences. The readers successively assessed individual sequences (T1, STIR, DWIBS), then pairs of sequences (T1/DWIBS, T1/STIR, STIR/DWIBS), and finally all sequences together (T1/STIR/DWIBS) to detect bone involvement. The gold standard was established on the basis of a panel review of all sequences.

RESULTS
Inter-observer agreement was good to excellent with similar kappa in both groups (.71 to .96). In the 'PCa' group, the study demonstrated the superiority of T1-weighted (Se 100%, Sp 92%) and DWI (Se 97%, Sp 92%) sequences, and of the pair T1/DWIBS (Se 100%, Sp 100%) for the detection of patients with bone involvement. Isolated reading of STIR sequences lacked accuracy (Se 91%, Sp 92%) for detecting bone metastases. In the 'MM' group, the study demonstrated the insufficiency of individual sequences (Se 83-93%, Sp 70%) to detect bone involvement. The best diagnostic accuracy was achieved by the combined reading of all sequences T1/STIR/DWIBS (Se 93%, Sp 88%).

CONCLUSION
To detect bone involvement, the combined reading of T1- and DWI-weighted sequences appears sufficient in PCa, whereas the combined reading of all sequences is necessary in MM.

CLINICAL RELEVANCE/APPLICATION
Diagnostic accuracy of the different sequences obtained in whole-body MRI (WB-MRI/DWI) are unknown. The combined reading of T1- and DWI-weighted sequences appears sufficient in PCa, whereas the combined reading of all sequences is necessary in MM.

SSA14-06 Correlation between Intravoxel Incoherent Motion Diffusion-weighted MR Imaging Parameters and Dynamic Contrast-enhanced MR Perfusion Parameters in Patients with Bone Metastasis from Non-Small Cell Lung Cancer at 3.0 T

Sunday, Nov. 29 11:35AM - 11:45AM Location: E451A

PARTICIPANTS
Na Hye Han, Seoul, Korea, Republic Of (Presenter) Nothing to Disclose
To retrospective investigate whether intravoxel incoherent motion (IVIM) diffusion-weighted imaging (DWI) parameters correlate with dynamic contrast-enhanced (DCE) magnetic resonance imaging (MRI) perfusion parameters in patients with bone metastasis from non-small cell lung cancer (NSCLC) at 3.0 T.

METHOD AND MATERIALS

The institutional review board approved this retrospective study and informed consent was waived. Thirty-two patients (16 men, 16 women, mean age 61 years, range 46-89) with 37 treatment naïve bone metastases from NSCLC underwent 3T MRI including IVIM DWI with nine b values (0-800 sec/mm^2) and DCE-MRI. Following IVIM parameters including apparent diffusion coefficient (ADC), true diffusion coefficient (Dslow), pseudodiffusion coefficient (Dfast), and perfusion fraction (f), DCE MRI perfusion parameters including volume transfer constant (Ktrans), rate constant (Kep), extravascular extracellular volume fraction (Ve), and initial area under the time-signal intensity curve at 60 seconds (iAUC) were calculated. The Spearman rank correlation was performed for statistical analysis.

RESULTS

Median Ktrans, Kep, Ve, and iAUC were 138 (107-213) 10^-3/min, 506 (319-647) 10^-3/min, 334 (236-513) 10^-3, and 16 (11-27), respectively. Median ADC, Dslow, Dfast, and f were 973 (849-1198) μm^2/sec, 898 (786-1128) μm^2/sec, 274 (224-311) μm^2/sec, and 98 (59-118), respectively. Ktrans demonstrated a significant inverse correlation with Dslow (r = -0.405, P = .013). Kep revealed a significant inverse correlation with ADC and Dslow (r = -0.370, P = .024; r = -0.352, P = .033, respectively). There was a significant inverse correlation of iAUC with ADC and Dslow (r = -0.434, P = .007; r = -0.486, P = .002, respectively). However, there was no significant correlation between Ve and IVIM parameters.

CONCLUSION

Ktrans inversely correlates with Dslow, while Kep and iAUC inversely correlate with ADC and Dslow in patients with bone metastasis from NSCLC at 3.0 T.

CLINICAL RELEVANCE/APPLICATION

IVIM DWI could help assume tumor perfusion in bone metastasis from NSCLC, particularly when DCE MRI cannot be performed.
Assessment of Therapeutic Response in Ewing's Sarcoma Based on One-, Two-, and Three-dimensiona...
In clinical practice, a high sensitivity of response assessments is warranted in order to avoid ineffective therapies and stratify non-responders to other therapies at a time point when interventions can still impact prognosis. Our data in EFST showed that volumetric tumor measurements are substantially more sensitive for detection of tumor non-response than unidimensional measurements.

**SSA13-01**  **Fluoroscopic Guided Sacroiliac Joint Injections - Comparison of Intra-articular and Peri-articular Injections on Immediate and Short-term Pain Relief**

Sunday, Nov. 29 10:45AM - 10:55AM Location: E451B

**Participants**

Nicholas C. Nacey, MD, Charlottesville, VA (Presenter) Nothing to Disclose
James Patrie, MS, Charlottesville, VA (Abstract Co-Author) Nothing to Disclose
Michael G. Fox, MD, Charlottesville, VA (Abstract Co-Author) Stockholder, Pfizer Inc;

**PURPOSE**

To determine if intra-articular sacroiliac (SI) joint injections provide greater immediate and short-term pain relief compared to peri-articular SI joint injections.

**METHOD AND MATERIALS**

All fluoroscopic guided SI joint injections targeting the inferior 1 cm of the SI joint, performed over a 4-year period, were identified. All patients were injected with 2.5 mL of Bupivacaine and 20 mg (0.5 mL) of triamcinolone. Patients were excluded if another triamcinolone dose or a different steroid/anesthetic combination was used, or if either the pre-injection, immediate (5-10 minute) post-injection, or 1-week post-injection pain score was not recorded. Two MSK radiologists with 2 and 13 years post-fellowship experience independently retrospectively reviewed the fluoroscopic images to determine intra-articular or peri-articular placement. Univariate and multivariate statistical analysis was performed.

**RESULTS**

169 patients (114F:55M; mean age 60.9 years) met the inclusion criteria with 88 intra-articular and 81 periarticular injections. Pre, immediate and 1-week post-injection pain scores for the intra-articular and periarticular injections were 6.2/2.0/4.1 and 6.0/2.3/4.2, respectively. Immediate and 1-week post-injection pain reduction was statistically significant in both groups (p <0.001). After adjusting for age, gender, pre-pain level, time of year, and reason for exam there was no significant difference in the pre-injection to immediate post-injection change in pain between intra-articular and periarticular injections (mean change 0.35, p=0.30) or in the pre-injection to 1-week postinjection change in pain (mean change 0.03, p=0.92). Geometric mean fluoro time was 27 sec for intra-articular injections and 42 sec for periarticular injections (p<0.001).

**CONCLUSION**

Both intra-articular and periarticular SI joint injections provide statistically significant immediate and 1-week post-injection pain relief. However, there was no significant difference in the degree of pain relief provided by intra-articular and peri-articular injections.

**CLINICAL RELEVANCE/APPLICATION**

Since similar pain relief was provided with intra-articular and periarticular SI joint injections, fluoroscopy is an adequate method for performing most SI joint injections.

**SSA13-02**  **Ten Years' Experience in Combined Intradiscal and Periradicular Injection of Medical Ozone and Periradicular Administration of Steroids and Anesthetic for the Treatment of Lumbar Disk Herniation: Effects on Disk Size and Lumbar Radiculopathy in 437 Patients**

Martin Beeres, MD, Frankfurt Am Main, Germany (Abstract Co-Author) Nothing to Disclose
Thomas J. Vogl, MD, PhD, Frankfurt, Germany (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To evaluate the therapeutic benefit and morphologic changes in herniated lumbar disk after CT-guided intradiscal and periradicular ozone-oxygen injection combined with a periradicular administration of steroids and anesthetic.

**METHOD AND MATERIALS**
437 patients with lumbar radiculopathy received an intradiscal (3 mL) and periradicular (7 mL) injection of an ozone-oxygen mixture (ratio 3:97), followed by a periradicular injection of corticosteroid (1 mL of Celestan®Depot) and anesthetic (2 mL of Carbostesin® 0.25%) in the same session. Under CT guidance, intradiscal and periradicular injection was administered by means of an extravascular lateral approach, using a 22-gauge 17.8-cm spinal needle. 6 months after treatment, clinical outcome was assessed by applying the modified MacNab method. The effects on disk matrix and disk volume were evaluated by MRI.

RESULTS
Treatment was successful in 316 patients (72.3%). In the remaining 121 patients (27.7%), treatment was considered to have failed. Among the patients whose treatment was a success, outcome was excellent in 153 patients (48.4%) and good in 163 patients (51.6%). Among the patients whose treatment was a failure, this was poor in 87 patients (71.9%) and poor with recourse to surgery in 34 patients (28.1%). Initial disk volume was 8.06-29.15 cm³ (mean, 18.29 cm³). 6 months after treatment, in patients with excellent outcome disk volume reduction was 5.67-22.11% (mean, 12.11%), in patients with good outcome 2.61-16.11% (mean, 7.29%) and in patients with poor outcome 0.33-8.21% (mean, 2.46%).

CONCLUSION
Our study shows that the combined intradiscal and periradicular injection of medical ozone and periradicular injection of steroids affects both the mechanical and the inflammatory components of pain caused by disk herniation. For this reason, this is a therapy option for treating lumbar disk herniation that has failed to respond to conservative management, before recourse to surgery or when surgery is not possible.

CLINICAL RELEVANCE/APPLICATION
CT-guided combined intradiscal and periradicular injection of ozone-oxygen represents a therapeutic alternative for lumbar radiculopathy with promising results. The ease of execution and non-invasiveness of this therapy permit the successful outpatient treatment of lumbar sciatic pain.

SSA13-03 Computed Tomography (CT) Guided O2-O3 Discolysis: Critical Review of Indications According to Our Experience

Sunday, Nov. 29 11:05AM - 11:15AM Location: E451B

Carlo Masciocchi, MD, L'Aquila, Italy (Abstract Co-Author) Nothing to Disclose
Massimo Gallucci, MD, L'Aquila, Italy (Abstract Co-Author) Nothing to Disclose

PURPOSE
The aim of this study was to clarify the O2-O3 discolysis indications and outcomes depending on the type of disc disease.

METHOD AND MATERIALS
Medical Ethical Committee approval was obtained for prospective double-blind trial. A total of 517 patients gave informed consent and were randomly assigned to two groups. Control group of 159 men and 101 women with age range 25-89 years, underwent percutaneous steroid treatment while Study Group of 163 men and 94 women with age range 22-92 years underwent the same treatment with the addiction of oxygen-ozone discolysis. Procedures were performed under computed tomographic guidance. Visual Analog Scale Questionnaire was administered before treatment and at intervals, the last at 6-month follow-up. Results were compared with the X2 and t-test.

RESULTS
After 6 months, O2-O3 discolysis was successful in 106 Study Group patients (41.24% with extrusions) compared with 9 Control Group patients (3.5%) with the same disco vertebral pathology (P <.001). Moreover in 89 (34.6%) Study Group patients with protrusions success rate was statistically significant (P<.001) compared with 5 Control Group patients (1.9%) with the same pathology. Furthermore statistically significant difference (P<.001) was detected in the presence of Grade I, II, III of Degenerated Disc in 185 of Study Group patients (68.4%) compared with 4 Control Group patients (1.5%).

CONCLUSION
O2-O3 discolysis is more effective at 6 months than steroid and anesthetic injection near intraforaminal sites especially in cases of sciatica due to herniated or protruded disc and with a Grade of Disc Degeneration from mild to moderate range.

CLINICAL RELEVANCE/APPLICATION
Our approach leads to relief in sciatica symptoms and obtains the best results in case of extrusions, protrusions and in presence of discal degenerative aspects from mild to moderate grade.

SSA13-04 Painful Langherans Cells Hystyocitosis of the Spine: CT- guided Percutaneous Injection of Corticosteroids

Sunday, Nov. 29 11:15AM - 11:25AM Location: E451B

Participants
Giancarlo Facchini, Bologna, Italy (Presenter) Nothing to Disclose
Paolo Spinnato, MD, Bologna, Italy (Abstract Co-Author) Nothing to Disclose
Alberto Bazzocchi, MD, Bologna, Italy (Abstract Co-Author) Nothing to Disclose
Danila Diano, Bologna, Italy (Abstract Co-Author) Nothing to Disclose
Eugenio Rimondi, MD, Bologna, Italy (Abstract Co-Author) Nothing to Disclose
Ugo Albisinni, MD, Bologna, Italy (Abstract Co-Author) Nothing to Disclose

PURPOSE
The purpose of our work was to analyse the role of CT-guided percutaneous injection of corticosteroids for painful Langherans Cells Hystiocytosis (LCH) of the spine.

METHOD AND MATERIALS

From 1991 at our Institute we have been treating painful LCH of the spine only with corticosteroids injection (40 mg of Depomedrol · metilprednisolone acetate). Until now we have carried out 32 injection: 5 cervical, 9 thoracic, 12 lumbar and 6 sacral. (14 males and 18 females, age 3-44 years, follow-up 0.6-17 years). All localizations were solitary at the onset. Before the injection a complete imaging study of the lesion (X-ray, CT and MRI) was performed; the final diagnosis was always made by CT-guided biopsy. We carried out three controls (only CT and MRI) at 2, 4 and 12 months; the 12-month check was performed in persistence of pain only.

RESULTS

In 30 cases (93,7%) the injection resulted in complete clinical healing. In 2 cases corticosteroids injection was repeated for lasting pain. In 2 patients we subsequently observed the involvement of other sites and tissues (pelvis, shoulder blade and lungs) with the diagnosis of systemic disease; for this reason they underwent chemotherapy. All patients showed radiological healing with restore of normal bone architecture.

CONCLUSION

CT-guided percutaneous injection of corticosteroids may be considered as a valid treatment approach for painful spinal LCH. This minimally invasive procedure allows reaching difficult anatomical sites (spine) with high accuracy.

CLINICAL RELEVANCE/APPLICATION

The safety and effectiveness of CT-guided percutaneous injection of corticosteroids in the treatment of painful spinal LCH suggest that this minimally invasive procedure can replace other treatment options.

SSA13-06 Magnetic Resonance Guided Focused Ultrasound Surgery (MRFUS) for Totally Non-Invasive Treatment of Osteoid Osteoma: A Prospective Development Study

Sunday, Nov. 29 11:35AM - 11:45AM Location: E451B

Participants

Maurizio Del Monte, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Gaia Cartocci, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Alessandro Napoli, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Valeria De Socco, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Fabrizio Boni, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Carlo Catalano, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose

PURPOSE

To investigate mid-to long-term efficacy of MRFUS in the treatment of symptomatic osteoid osteomas

METHOD AND MATERIALS

This prospective study involved 29 consecutive patients with clinical and imaging diagnosis of Osteoid Osteoma; all patients underwent MRFUS ablation (ExAblate, InSightec; 3T MR).Lesions located in vertebral body were excluded; prior RFA or surgery was not considered an exclusion criteria. Patients received therapy using MRFUS, delivered toward the nidus, identified on MRI and/or CT. Primary endpoints were adverse events (serious and otherwise) and pain relief assessed using Quality of Life questionnaires in patients with bone pain (FACT-BP), Visual Analog Pain Score (VAS) and daily intake of Non-steroidal anti-inflammatory drugs (NSAIDs). Patient’s follow-up, including clinical and imaging examinations, was established at 1, 12 and 24 months. As secondary endpoint, imaging examinations (CT and dynamic CE-MRI, Gd-BOPTA, Bracco) were used to evaluate inflammatory status after treatment and bone remodeling.

RESULTS

29 patients (4 female; 25 male; mean age 23,4 yo) were recruited for totally non-invasive MRFUS treatment. The treatment was well tolerated by all patients and no adverse events were recorded. A mean number of 5.6 soninations with mean energy of 894 ± 209 J was necessary to complete the treatment. Complete clinical response was found in 27/29 patients. There was a significant (p=0.001) improvement in quality of life, according to FACT-BP (mean values: 33.7 at baseline and 54.7 at follow-up). A statistically significant difference (p=0.001) was noted between pre-and post-treatment VAS scores (8.4 vs 0.6, respectively). Imaging evaluation with CE-MRI demonstrated edema and hyperemia decrease in lesions associated with complete response. At CT, bone remodeling was evident in all complete responders (27/29 patients, 93%); in 15/29 (51%), nidus fading was demonstrated and in 10/29 (34%) restitutio-ad-integrum of bone abnormality was depicted.

CONCLUSION

MRFUS can be safely and effectively adopted for the treatment of Osteoid Osteoma. This application is totally non-invasive, carried out in a single session and with pain relief attainable since the very following day after treatment. Our results also indicated a positive trend to bone restoration especially in younger patients.

CLINICAL RELEVANCE/APPLICATION

MRFUS allows single session, totally non-invasive treatment of osteoid osteoma.

SSA13-07 Minimally Invasive Screw Fixation of Fractures in the Cervical and Thoracic Spine: CT-controlled Percutaneous Guidewire Implantation in Clinical Routine

Sunday, Nov. 29 11:45AM - 11:55AM Location: E451B

Participants

Sebastian Fischer, MD, Frankfurt, Germany (Presenter) Nothing to Disclose
Thomas J. Vogl, MD, PhD, Frankfurt, Germany (Abstract Co-Author) Nothing to Disclose
PURPOSE
Purpose of our retrospective study is to evaluate the feasibility and accuracy of minimally invasive, transpedicular screw placement in cervicothoracic fractures with the help of CT-controlled guidewires.

METHOD AND MATERIALS
293 guidewires were inserted in 35 patients (42.9 ± 21.2 years) under CT fluoroscopy (286 thoracic, 7 cervical). There were 28 traumatic cases, 3 pathologic fractures, 3 fractures due to infectious infiltrations and 1 osteoporotic fracture. In 151 pedicles the screwing was directly performed and controlled in the CT-room. CT-images were reviewed regarding accuracy and cortical violations using the popular 2 mm increment deviation classification by Gertzbein and Robbins.

RESULTS
The guidewire implantation resulted in 28 cortical contacts. Minor affections of the pedicle wall by the inserted screws occurred in 39.1% (59 of 151), respectively 23.8% if taking unavoidable encroachments into account (30 of 59). The width of the pedicular isthmus correlated to the number of cortical guidewire-contacts (r=-0.449; p=0.077) and pedicle violations (all graded “A”) by the inserted screws (r=-0.581; p=0.049). Total procedural duration was 138.6 ± 44.2 min, representing 14.5 ± 11.6 min for each pedicle, while showing a significant negative correlation against the vertebral level [r=-0.849; p=0.0002] and the occurrence of pedicle violations (r=-0.641; p=0.027).

CONCLUSION
The treatment of vertebral fractures with a guidewire-based insertion technique for pedicle screws results in a very high accuracy and a low complication rate if performed under CT-imaging.

CLINICAL RELEVANCE/APPLICATION
Guidewires help in precise placement of cervical and thoracic screws for vertebral osteosynthesis. Special attention should be taken in the mid-thoracic levels due to a smaller width of the pedicle isthmus.

SSA13-08 Feasibility of CT Guided Needle Biopsy in Harvesting Chondrocytes for Autologous Chondrocyte Implantation: An Initial Experience on Human Cadavers
Sunday, Nov. 29 11:55AM - 12:05PM Location: E451B

Participants
Nima Hafezi Nejad, MD, MPH, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Shadpour Demehri, MD, Baltimore, MD (Presenter) Research support, General Electric Company; Researcher, Carestream Health, Inc; Consultant, Toshiba Corporation
Bashir Zikria, Baltimore, MD (Abstract Co-Author) Nothing to Disclose

PURPOSE
To evaluate the timing, accuracy and technical feasibility of CT guided chondrocyte retrieval from superior medial and lateral non weight-bearing margins of the trochlea.

METHOD AND MATERIALS
As an initial experience, 10 human knee cadavers were selected as samples. Osteosite bone biopsy needle (G13761 - Murphy M1M - 11G/10cm) was used for the purpose of chondrocyte retrieval. Two operators, one musculoskeletal radiologist and one orthopedic surgeon performed the chondrocyte retrieval procedures. Each performed one sampling from the medial and one sampling from the lateral margins of trochlea. In the first planning phase, operators selected the proper target for chondrocyte retrieval, in the CT examination. Time (seconds), accuracy (mm distance from the target) and needle readjustment attempts were recorded during chondrocyte retrieval.

RESULTS
All samplings resulted in eventual tissue retrieval. Samplings from the lateral margin were performed faster (Operator 1: 74 ± 34 sec vs. 106 ± 36 sec; P value: 0.056 - Operator 2: 72 ± 30 sec vs. 111 ± 35 sec; P value: 0.014) and more accurate (Target error: Operator 1: 1.32 ± 1.01 mm vs. 3.23 ± 1.72 mm; P value: 0.007 - Operator 2: 1.17 ± 0.57 mm vs. 2.81 ± 1.36 mm; P value: 0.040) than samplings from the medial margin. There was no significant difference in the mean number of needle adjustment rates (ranging from 1.50 ± 0.71 to 1.10 ± 0.74 readjustment attempts); neither between the operators, nor between lateral and medial margins.

CONCLUSION
This preliminary results supports the hypothesis that CT guided needle biopsy may be a feasible and accurate method for chondrocyte retrieval from non weight-bearing margins of the trochlea. Sampling from the lateral margin may be relatively advantageous in terms of procedure time and accuracy.

CLINICAL RELEVANCE/APPLICATION
Feasibility of CT-guided chondrocyte retrieval for autologous chondrocyte implantation may obviate one arthroscopic surgery; and therefore, reduce the cost, morbidity and complication.

SSA13-09 US and MRI Follow-up after Treatment of Supraspinatus Tendon Tendinopathy: PRP vs Needling
Sunday, Nov. 29 12:05PM - 12:15PM Location: E451B

Participants
Alice La Marra, MD, L'Aquila, Italy (Presenter) Nothing to Disclose
PURPOSE
To evaluate the efficacy of infiltrative treatment with PRP versus needling, in patients with tendinosis of the supraspinatus tendon at level of its crescent area.

METHOD AND MATERIALS
We enrolled 40 patients (aged 40-60), with tendinosis of the supraspinatus tendon at its crescent area, evaluated through ultrasound-US and MRI exams; we excluded patients with partial lesions. Twenty patients were submitted to PRP treatment (group 1); 20 patients were submitted to needling treatment (group 2). All patients, 6 months after treatment (T1) underwent US examinations and 1 year after treatment (T2) underwent US and MRI examinations. We considered some fundamental parameters: morphology of the tendon, echogenicity or signal intensity of its structures, presence or not of bursitis, evolution in partial or full tear. All patients were evaluated through VAS (Visual Analogic Scale) for pain and Constant scale for functionality.

RESULTS
In group 1, at T1 the ultrasound exams showed disappearance of bursitis and recovery of tendon echogenicity in 15/20 patients; 5 patients had no changes. At T2, in 17/20 patients MRI and US showed morphological recovery; we observed non-substantive modifications in 2 patients and a worsening in 1 patient. 85% of the patients showed improvement in VAS and 77% in Constant values already at T1; the mean values were 70% at T2. In group 2, at T1, US showed disappearance of bursitis and recovery of tendon echogenicity in 8/20 patients; 12 patients showed no changes. At T2 in 6/20 patients, MRI and US showed morphological recovery; 8 patients had no significant variations; 4 patients had worsening of tendinosis; 2 patients showed partial tears of the tendon. 65% of the patients showed improvement in VAS and 62% in Constant values at T1; the mean values were only 33% at T2.

CONCLUSION
Compared to needling, the PRP infiltrative treatment of tendinosis of the supraspinatus tendon showed major possibilities of recovery, with a slower evolution of tendinosis or tendon's tear.

CLINICAL RELEVANCE/APPLICATION
Both PRP and needling are effective minimally invasive treatments suitable for large range of patients. PRP resulted to be more effective with a lower rate of progression of the tendinosis or tendon tear.
**PURPOSE**

Parotidectomy with facial nerve (VII\textsubscript{n}) sacrifice is often necessary in patients with malignant tumor. In all parotid masses, diagnosis of perineural spread is important as a prognosis biomarker since patients may have asymptomatic nerve invasion. Recently, the feasibility of intraparotid VII\textsubscript{n} tractography was assessed to identify nerve contact with parotid tumors. The aim of this study was to determine if VII\textsubscript{n} fractional anisotropy (FA) was linked to histologic grade in patients undergoing surgery for parotid tumors.

**METHOD AND MATERIALS**

Study ethics approval was obtained from our institutional review board (IRB 5891). Patients aged 18 or over, were including in this prospective study if they had: (a) A history of parotid tumors, requiring surgical management between December 2013 and April 2015; (b) Undergone MR scans with diffusion acquisition and post-processing tractography (c) Surgical intraoperative checking of the intraparotid facial nerve. Patients underwent MR scans with VII\textsubscript{n} tractography calculated with the constrained spherical deconvolution model. We performed scans on a 3T MRI Philips ACHIEVA\textsuperscript{®} 3.0T TX with a 32 channel head coil. The post-processing steps were performed using MRtrix package software. The parameters of the diffusion sequence were: b-value of 1000 s/mm\textsuperscript{2}, 32 directions, voxel size: 2 mm isotropic, scan time: 9'31''.

**RESULTS**

Twenty patients (mean age: 53 years, 5 women) were enrolling in this study. The first group (n=10) referred with a benign tumor without facial nerve compression or invasion as checked by surgical team. The second group (n=10) referred with a malignant tumor and included three patients with clinical facial nerve palsy. The VII\textsubscript{n} mean FA value was estimated as being 0.53±0.06 in patients with benign tumors and 0.37±0.08 in malignant tumor group. Mean FA value was significantly lower in the second group (t-test, p=0.05) and was also reduced in patients free from clinical facial palsy with surgically evidence of VII\textsubscript{n} perineural spread (p=0.03).

**CONCLUSION**

In these preliminary results, MRI using diffusion tractography was a promising procedure to assess parotid tumor histologic grade and potential perineural spread.

**CLINICAL RELEVANCE/APPLICATION**

A reliable imaging biomarker of histologic grade and perineural spread in cases with parotid tumors may help to better inform and manage patients.
Additive Value of "Otosclerosis Weighted" Images for the Diagnosis of Fenestral Otosclerosis

PURPOSE
CT is one of the main diagnostic tools for the detection of otosclerotic foci which are often identified as low density lesions in the ante fenestral region. Bone densities can be measured in Hounsfield units by the accurate regions of interest (ROIs) setting. However, small ROI settings by less-experienced radiologists may result in false negative findings. Our purpose was to evaluate the diagnostic ability of our proposed method (otosclerosis weighted image) compared with conventional CT images alone.

METHOD AND MATERIALS
Temporal bone CT of consecutive patients with otosclerosis were retrospectively analyzed. The diagnosis of otosclerosis was confirmed during surgery in all cases. All CT images were obtained using a sixty-four-detector-row CT scanner with 0.5-mm collimation, 80 mm FOV, and a 512 × 512 matrix. "Otosclerosis weighted" images were obtained by extracting temporal bone region with threshold technique and reversing the density gradients (black to white). Two independent radiologists took part in two reading sessions. In the first session, the observers read only conventional CT images. In the second session they read "otosclerosis weighted" images along with the conventional CT images. Accuracy was assessed for the two readers (Chi-square test).

RESULTS
Thirty temporal bones of 25 patients with otosclerosis (M:F = 3:22, mean age: 53.9±9.0 years old) were included. For both observers, reading with "otosclerosis weighted" image was associated with higher sensitivity (66.7-76.7%) than with the conventional CT images alone (50-56.7%; p<0.005, each).

CONCLUSION
MR imaging using Diffusion Weighted (DW) images and delayed gadolinium enhanced T1 weighted images is evolving into an alternative to second look surgery in detection of recurrent cholesteatomas. The aim of this study was to retrospectively compare the DW images, the post-gadolinium T1 weighted images and the combination of both methods in this indication.

METHOD AND MATERIALS
We retrospectively evaluated the MR examination of 39 patients clinically suspected for a recurrent cholesteatoma. Patients in the study underwent DW sequences, delayed gadolinium enhanced T1 weighted sequences as well as standard uninjected protocol using T1 and T2 sequences. Three blinded radiologists evaluated three data sets: a set of post-gadolinium T1 weighted images, a set of DW images and a set of the combination of both methods. The interobserver agreement was evaluated and the diagnostic accuracy of each method was described by sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV). The performances of the three techniques were also evaluated using ROC curves, from which the AUC were compared. Results were compared with surgical results or a two-year follow-up.

RESULTS
The overall sensitivity and specificity were respectively 63 % and 71 % for the post-gadolinium T1 weighted images, 88 % and 75 % for the DW images and 84 % and 75 % for the combined images. The PPV and NPV were respectively 89 % and 33 % for the post-gadolinium T1 weighted images, 93 % and 62 % for the DW images and 93 % and 55 % for the combined images. The sensitivity and the NPV were significantly different between the three methods (P < 0.0001 and P = 0.027). There was no statistically significant difference in specificity or PPV between the three methods (P = 0.931 and P = 0.650). The diagnostic accuracy evaluated with the AUC showed no statistically significant difference between the DW images and the combined images (P = 0.433).

CONCLUSION
MR imaging reliably identifies those patients suspected for recurrent cholesteatoma who require a surgical second look by using DW MR imaging.

CLINICAL RELEVANCE/APPLICATION
The combination with delayed gadolinium enhanced T1 weighted sequences does not significantly increases the diagnostic accuracy of the examination.
Application of our proposed method based on threshold value may help reduce misdiagnosis of fenestral otosclerosis.

**CLINICAL RELEVANCE/APPLICATION**

CT is one of the main diagnostic tools for the detection of otosclerotic foci which are often identified as low density lesions. Application of our method based on threshold value helps reduce misdiagnosis of fenestral otosclerosis.

**SSA16-04 Preserved Cochlear T2 Signal is an Important Predictor for Hearing Preservation in Patients Treated for Vestibular Schwannoma**

Grish M. Fatterpek, MBBS, New York, NY (Abstract Co-Author) Editor, Reed Elsevier

**PURPOSE**
Hearing preservation is a therapeutic goal for many patients with vestibular schwannoma (VS). We examined the relationship between pre-treatment MRI and post-treatment hearing status in an effort to define factors that may influence management.

**METHOD AND MATERIALS**
From September 2010 through January 2014, consecutive cases of VS treated with stereotactic radiosurgery (SRS) or microsurgery were reviewed. Preoperative MRIs were analyzed by two readers with respect to three dimensional tumor size, shape (round vs. oval), cochlear T2 signal, relationship of tumor to internal auditory canal (IAC), and presence of necrosis. Patients were excluded if they had prior treatment or no pre-treatment MRI within one year. "Serviceable" hearing was defined as speech discrimination score (SDS) ≥70% or AAO-HNS class A/B. Post-treatment hearing "preservation" was defined as maintenance or development of serviceable hearing after SRS or microsurgery using non-translabyrinthine approach. Bivariate statistics were calculated.

**RESULTS**
191 cases were reviewed; 68 patients met criteria for inclusion. A majority underwent SRS (69%), had tumors in the distal IAC (52%), oval shape (56%), without confluent necrosis (68%), and median volume of 0.95 mL. Of these patients, 55 and 30 had pre- and post-treatment audiology, respectively; 56% and 67% had "serviceable" pretreatment hearing on SDS and AAO-HNS, respectively. People without serviceable pretreatment hearing on SDS and AAO-HNS had significantly larger (p=0.05) and round (p=0.02) tumors. Reduced cochlear T2 signal trended towards worse hearing on AAO-HNS (p=0.12). Preserved cochlear T2 signal was the only variable significantly associated with post-treatment hearing preservation as measured by SDS or AAO-HNS in all tumors (p<.001 and p=.01, respectively) or SDS for those in the distal IAC (p=0.02). Interobserver agreement measuring cochlear T2 signal was 92%.

**CONCLUSION**
Preoperative MRI identified patients more likely to have better hearing outcomes, thus aiding clinicians in pretreatment counseling. Decreased cochlear T2 signal may indicate close association with the cochlear neurovascular bundle, influencing endolymph protein concentration and negatively influencing hearing outcome.

**CLINICAL RELEVANCE/APPLICATION**
Pre-treatment cochlear T2 signal is associated with hearing outcomes after treatment for vestibular schwannoma. Use of thin section MRI has the potential to better inform treatment decisions.

**PURPOSE**
To assess the clinical feasibility of MR slip interface imaging (SII) for predicting the degree of tumor-brain adhesion in vestibular schwannomas.

**METHOD AND MATERIALS**
With IRB approval and informed consent, nine patients with pathologically suspected and subsequently confirmed vestibular schwannomas were recruited. The SII acquisition is similar to MR elastography (MRE) in which low-amplitude mechanical vibration is applied to the head with a pillow-like device placed in the head coil and the resulting shear waves are imaged using a phase-
contrast pulse sequence with motion encoding gradients synchronized with the applied vibration. Imaging was performed on a 3T MR system with an 8-channel head coil in a scan time of less than 7 minutes. The acquired shear motion data were processed with two different algorithms (shear line analysis and calculation of octahedral shear strain (OSS)) to identify the degree of tumor-brain adhesion. Blinded to the SII results, neurosurgeons qualitatively assessed tumor adhesion at the time of tumor resection as one of three patterns: no adhesion, partial adhesion, and complete adhesion. Correlations between SII and surgical findings were determined, and the ability to use OSS to quantify the tumor adhesion was tested using a Mann-Whitney U test with a statistical significance set at p < 0.05.

RESULTS
In SII, the presence of a non-adhesive tumor-brain interface appears as a dark line in the shear line images and exhibits higher OSS values than an adhesive interface. The absence of shear lines corresponded to complete tumor adhesion. Surgical results for the nine patients included 2 cases with complete adhesion, 3 with partial adhesion, and 4 with no adhesion. SII results were concordant with the intraoperative assessment of tumor adhesion in 8 cases (88.9%). One case was identified as having no adhesion with SII, but adhesions were found at surgery. The OSS values for the non-adhesive interfaces were significantly larger (p=0.012) than the adhesive interfaces.

CONCLUSION
Our results demonstrate that SII is a clinically feasible method to preoperatively predict the degree of tumor-brain adhesion in patients with vestibular schwannomas.

CLINICAL RELEVANCE/APPLICATION
The SII technique shows promise for allowing radiologists and neurosurgeons to preoperatively quantify the degree of intracranial tumor adhesion and predict potential complications of tumor resection.

SSA16-06 Endolymphatic Hydrops as an Imaging Biomarker: A Chronic Disease with Various Clinical Presentations

Sunday, Nov. 29 11:35AM - 11:45AM Location: N226

PURPOSE
MRI seeking for endolymphatic hydrops (EH) was recently found as closely reflecting histopathologic findings in patients with Meniere's disease (MD). However, the lack of healthy subject data was problematic to precisely define the pathological condition. The aim of this study was to assess EH prevalence in a large cohort of patients with four clinical presentations: MD, sensorineural hearing loss (SHL), recurrent peripheral vestibulopathy (RPV) and recurrent benign paroxysmal positional vertigo (rBPPV) in comparison with healthy subjects. We also evaluated EH localization (i.e cochlear or vestibular) in each group.

METHOD AND MATERIALS
300 patients and 25 healthy subjects were recruited between January 2013 and May 2015. Patients were consecutively included in this study if they had:(a) A history of clinically defined MD (n=100), RPV (n=100), SHL (n=50) or rBPPV (n=50)(b) Have undergone an MRI scan 4 hours after intravenous gadoteric acid injection using FLAIR imaging (TR: 8000 ms, TE: 316 ms, TI: 2400 ms) with subtraction process. Control subjects inclusion was approved by our institutional review board (IRB 6705/15-CHUG-02). Two radiologists performed blind, semi-quantitative evaluations of MRI scan. Cochlear EH have been noted as present if nodular or irregular dilatation of endolymphatic canal and VH recorded as present when more than 50% of the vestibule have been occupied by endolymphatic space. Patients were graded based on the number and localization of hydrops and results were analyzed using the Student’s t-test.

RESULTS
300 patients and 25 healthy subjects were included in this study. EH prevalence was approximately estimated as being 85%, 50%, 40% and 40% in MD, SHL, RPV and rBPPV groups respectively. The results showed a significantly higher average number of hydrops localizations in the MD group when compared to other groups (t-test, p<0.01). Cochlear EH was found in 36% and 38% of RPV and rBPPV patients. Vestibular EH was displayed in 20% of SHL patients.

CONCLUSION
Our results demonstrate that SII is a clinically feasible method to preoperatively predict the degree of tumor-brain adhesion in patients with vestibular schwannomas.

CLINICAL RELEVANCE/APPLICATION
The SII technique shows promise for allowing radiologists and neurosurgeons to preoperatively quantify the degree of intracranial tumor adhesion and predict potential complications of tumor resection.

SSA16-07 Superiority of Heavily T2-weighted 3D-FLAIR Over Regular 3D-FLAIR for the Detection of Cochlear Lymph Fluid Signal Abnormality in Patients with Sudden Sensorineural Hearing Loss

**SSA16-08** Three-Dimensional Fluid-Attenuated Inversion Recovery Signal Changes as a Prognosis Predictor in Idiopathic Sudden Sensorineural Hearing Loss

Sunday, Nov. 29 11:55AM - 12:05PM Location: N226

**PURPOSE**
To compare the signal increase of cochlear lymph fluid on 3D-FLAIR in patients with sudden sensorineural hearing loss (SNHL) between the regular contrast 3D-FLAIR (FL) and heavily T2-weighted 3D-FLAIR (HF).

**METHOD AND MATERIALS**
25 patients with unilateral sudden SNHL and 8 healthy volunteers were included. Patients were divided into mild group of 9 patients, average hearing level of 60 dB or less; and severe group of 16 patients, hearing level of more than 60dB. All patients and healthy volunteers underwent a MR cisternography (MRC) for anatomical reference of the fluid space, FL and HF at 3T. Region of interest (ROI) was manually drawn on mid-modiolar section of MRC around cochlea. ROI for noise was drawn in the air area. ROIs were copied onto FL and HF. Contrast-to-noise ratio (CNR) between affected and non-affected ear was measured in patients’ group and CNR between right and left ear was measured in control group. Differences in CNR on FL and HF among 3 groups were tested by one-way analysis of variance (ANOVA).

**RESULTS**
There was a statistically significant difference in the mean of CNR on HF among the three groups (p < 0.001). Further, from the pairwise comparisons among them, there was a statistically significant difference with each other in the mean of CNR on HF (p < 0.05). There was no statistically significant difference in the mean of CNR on FL among the three groups (p = 0.074).

**CONCLUSION**
HF is more sensitive to signal alteration of cochlea with sudden SNHL than FL.

**CLINICAL RELEVANCE/APPLICATION**
Heavily T2-weighted 3D-FLAIR (HF) is more sensitive to high signal of cochlea in the ears with sudden sensorineural hearing loss (SNHL) than regular contrast 3D-FLAIR (FL).

**SSA16-09** Flat Panel CT in Diagnosis of Superior Canal Dehiscence. A Really New Diagnostic Approach?

Sunday, Nov. 29 12:05PM - 12:15PM Location: N226

**PURPOSE**
To investigate the relationship of 3D FLAIR findings and outcome in patients with idiopathic sudden sensorineural hearing loss (ISSNHL).

**METHOD AND MATERIALS**
We retrospectively reviewed consecutive 66 patients presenting with unilateral ISSNHL from June 2013 to September 2014. Before treatment, all patients underwent MRI exams, including 3D-FIESTA, and 3D-FLAIR without gadolinium enhancement. One blind observer registered 3D-FIESTA and 3D-FLAIR on a dedicated workstation and drew ROIs to measure the signal intensity of cochlea in both affected and unaffected ears on 3D-FLAIR.

**RESULTS**
The ratio of the cochlear signals between the affected and unaffected ears showed significant correlation with the severity of pre-treatment hearing loss and the clinical outcome (Siegel criteria) after treatment. The increased FLAIR signal intensity is a specific prognostic predictor of poorer outcome (Siegel grade III/IV) after treatment. (sens./spec: 32%/86% (cutoff value: 1.2) and 5%/91% (cutoff value, 1.4)).

**CONCLUSION**
This study demonstrated a correlation between cochlear FLAIR signal and pre-treatment hearing level, and post-treatment outcome. Increased FLAIR signal is a specific prognostic predictor of poorer outcome after treatment.

**CLINICAL RELEVANCE/APPLICATION**
The causes of sudden deafness now are still idiopathic. In general, labyrinthitis caused by viral infection, blood circulation disorders, or ruptures of the inner ear membrane are believed to cause sudden deafness. The unpredictability of idiopathic sudden sensorineural hearing loss (ISSNHL) presents a challenge to preventive care. Prognosis can be predicted that the patients poor post-treatment outcome from the high intensity signal inner ear of 3D FLAIR sequence on MRI.
PURPOSE
Superior canal dehiscence (SCDS) is a rare defect, caused by a thinning or complete absence of temporal bone overlying superior semicircular canal of vestibular system. Treatment of choice is covering the defect with ceramic implant. Flat panel CT is an innovative technique that permits visualization of the complex anatomy of temporal bone with high spatial resolution. The utility of flat panel CT has been demonstrated in multiple disease states including neurovascular disease, peripheral vascular disorders and oncology. We therefore evaluated flat panel CT in diagnosis of SCDS.

METHOD AND MATERIALS
30 patients (m = 18/ f = 12) age 36 - 63 (m= 48.2) with symptoms of SCDS underwent flat panel CT examination between January 2013 and January 2015. 13 patient underwent MSCT imaging before, these images were assessed as normal. Flat panel CT was performed by Siemens Axiom Artis, rotation 220°. Postprocessing was done at Siemens Leonardo workstation with reconstructions in bone window in 3D projection and adapted to superior semicircular canal. Applied Radiation dose inbetween flat panel CT and MSCT was compared.

RESULTS
In 5/17 (29%) patients who underwent flat panel CT imaging SCDS was confirmed. In 6/13 (46%) patients who underwent MSCT and flat panel CT defect of temporal bone overlying superior semicircular canal was found and SCDS was intraoperatively confirmed. Applied radiation dose was nearly equal (flat panel CT 276.5mGy/ cm / MSCT 277.4mGy/ cm).

CONCLUSION
Flat panel CT should be performed in cases with symptoms SCDS when MSCT is assessed normal. It is a reliable diagnostic tool and a new diagnostic approach in diagnosis of SCDS.

CLINICAL RELEVANCE/APPLICATION
Flat panel imaging is a reliable tool in imaging temporal bone and inner ear structures and can improve preoperative virtual planning.
Neuroradiology/Head and Neck (Vascular Disease of the Head and Neck)

SSA17-01 The CTA Rim Sign: Calcification Pattern Predicts Carotid Intraplaque Hemorrhage

PURPOSE
Carotid intraplaque hemorrhage (IPH) is associated with a high risk of future stroke. The gold standard for IPH detection is MRI with heavily T1-weighted sequences. This study was undertaken to determine essential CTA imaging predictors of carotid IPH.

METHOD AND MATERIALS
In this IRB-approved retrospective cross sectional study, 172 patients (244 carotid arteries) were studied having undergone carotid disease workup with both MRA and CTA from 2009-present. IPH was detected with the Magnetization Prepared Rapid Acquisition Gradient-recalled Echo (MPRAGE) sequence. CTA predictors included the presence or absence of calcification, type of calcification (rim, adventitial or bulky), percent diameter stenosis, mm stenosis, maximum plaque thickness, ulceration, and intraluminal thrombus. Clinical covariates included age, male sex, diabetes, hypertension, hyperlipidemia and body mass index. Cardiovascular medication confounders included antihypertension, antiplatelet, anticoagulation and statin medication classes. A mixed effects multivariable Poisson regression model was used accounting for 2 vessels per patient. A backwards-elimination method was used to determine the final model, in which prevalence ratios were reported and all remaining predictors had a p<.10. ROC analysis was used to determine discriminatory power measured by area under the curve (AUC).

RESULTS
The final model for carotid IPH prediction included the rim sign (prevalence ratio, PR=8.6, p<.001, 95%CI: 4.0,18.5) and maximum plaque thickness (PR=1.2, p=.001, 95%CI: 1.1,1.4). In the final model, no other imaging criteria were significant predictors of IPH. The discriminatory value of the final model was extremely high (AUC=93.9%), significantly higher than the rim sign alone (86.1%, p<.001), thickness alone (85.2%, p<.001), NASCET stenosis (78.4%, p<.001), mm stenosis (77.7%, p<.001) or ulceration (71.0%, p<.001).

CONCLUSION
The carotid CTA rim sign is highly predictive of carotid IPH.

CLINICAL RELEVANCE/APPLICATION
Because most patients undergoing acute stroke workup receive lumen imaging with CTA, MRI is often not performed and IPH is ignored. The CTA rim sign and maximum plaque thickness allow high discrimination of carotid IPH. Future prospective studies may be envisioned to determine if the rim sign indicates a higher future stroke risk.

SSA17-02 Clinical Risk Prediction Models for the Identification of Patients with High-Risk Carotid Plaque

PURPOSE
High-risk carotid plaque containing intraplaque hemorrhage predicts stroke, however, it is not yet routinely screened for in practice. We aimed to develop cross-validated clinical models to identify patients at risk of high-risk carotid plaque.

METHOD AND MATERIALS
Between 2003 and 2014, 1862 suspected neurovascular disease patients had MRI. High-risk carotid plaque was defined by presence of intraplaque hemorrhage on 3D T1w GRE black-blood MRI, a sequence routinely included in our institutional neurovascular MRI protocol. Using derivation and validation cohorts with 931 patients each, two risk-prediction logistic regression models considering 11 risk factors, with and without inclusion of stenosis grade, were developed. Receiver-operator characteristic curves were used to compare discriminatory ability of these two models.

RESULTS
The overall prevalence of high-risk carotid plaque was 19.3% (359/1862). Patients with high-risk carotid plaque could be identified...
The overall prevalence of high-risk carotid plaque was 19.3% (95% CI 0.729 to 0.802). Patients with high-risk carotid plaque could be identified using age, sex, hypercholesterolemia, and peripheral vascular disease (AUC 0.781, 95% CI 0.747 to 0.815). Optimal threshold sensitivity and specificity was 81.8% and 62.4%, respectively. The addition of carotid stenosis grade improved discrimination of patients (AUC 0.826, 95% CI 0.799 to 0.856), and improved optimal threshold specificity to 72.8% without a significant change in sensitivity.

CONCLUSION
Patients prone to high-risk carotid plaque, containing intraplaque hemorrhage, may be identified using a simple clinical risk prediction model of cardiovascular risk factors and carotid stenosis grade.

CLINICAL RELEVANCE/APPLICATION
The model provides an opportunity for targeted carotid MRI screening in patients not already undergoing neurovascular MRI, but external validation studies are required.

SSA17-03  Identification of the Vulnerable Carotid Plaque Using Dynamic Contrast Enhanced Ultrasound

Sunday, Nov. 29 11:05AM - 11:15AM Location: N227

Participants
Brahman Dhammaraajah, MBBS, MRCS, London, United Kingdom (Presenter) Nothing to Disclose
Michalakis A. Averkiou, PhD, Seattle, WA (Abstract Co-Author) Nothing to Disclose
Damiano Christofides, MSc, Nicosia, Cyprus (Abstract Co-Author) Nothing to Disclose
Ankur Thapar, MBBS, MRCS, London, United Kingdom (Abstract Co-Author) Nothing to Disclose
Alun Davies, FRCR, London, United Kingdom (Abstract Co-Author) Nothing to Disclose

PURPOSE
Carotid atherosclerosis is implicated in 15-20% of all strokes. Dynamic contrast enhanced ultrasound (DCEUS) is a simple adjunct to color Doppler ultrasound for the assessment of carotid atherosclerosis. It has been identified that DCEUS can demonstrate perfusion within carotid plaques of greater than 50% stenosis with some differentiation observed between symptomatic and asymptomatic patients. In this study the perfusion of carotid plaques is evaluated both qualitatively and quantitatively to evaluate carotid perfusion of symptomatic and asymptomatic patients.

METHOD AND MATERIALS
After ethical approval, the carotid arteries of 24 patients were imaged using the L9-3 probe of the Philips iU22 ultrasound platform. Patients were injected with a bolus of 2ml of Sonovue with subsequent dynamic phase imaging acquisition. Offline blinded analysis was performed using DICOM data transferred to QLAB commercial analysis software. Qualitative perfusion assessment used binary grading: 0 represented less than 50% of carotid plaque area contained moving microbubbles and 1 represented more than 50% of carotid plaque area contained moving microbubbles. Static reflectors were not considered as valid microbubble signal. For quantitative DCEUS analysis, a region-of-interest (ROI) was drawn around the plaque. Plaques were delineated from the lumen signal to remove potentially large amplitude differences between the plaque and lumen signal intensity. A time intensity curve (TIC) was derived from the dynamic phase ROI signal with mean plaque intensity signal calculated from the TIC.

RESULTS
The qualitative analysis results showed that 75% (9/12) of asymptomatic patients had >50% carotid plaque perfusion in comparison to only 33% (4/12) of symptomatic patients. After quantitative image analysis, the mean DCEUS intensity signal from the TIC of the carotid plaques was again significantly higher for asymptomatic patients than symptomatic patients (P<0.05).

CONCLUSION
Contrary to previous studies, this study suggests that patients with greater carotid plaque perfusion are more likely to have an asymptomatic carotid symptom status where as those with reduced perfusion are more likely to be symptomatic from their carotid disease.

CLINICAL RELEVANCE/APPLICATION
In patients with greater than 50% carotid stenosis, reduced plaque perfusion on DCEUS may represent vulnerable, symptomatic carotid atherosclerosis.

SSA17-04  The Study of Symptomatic Atherosclerotic Plaque of Middle Cerebral Artery by In Vivo MRI-Based 3D Fluid-Structure Interaction

Sunday, Nov. 29 11:15AM - 11:25AM Location: N227

Participants
Wenjie Peng, MD, PhD, Shanghai, China (Presenter) Nothing to Disclose
Zhongzhao Teng, PhD, Cambridge, United Kingdom (Abstract Co-Author) Nothing to Disclose
Yuanliang Jiang, Shanghai, China (Abstract Co-Author) Nothing to Disclose

Qi Lu, MD, PhD, Shanghai, China (Abstract Co-Author) Nothing to Disclose
Jianping Lu, MD, Shanghai, China (Abstract Co-Author) Nothing to Disclose

PURPOSE
Based on the in vivo high-resolution magnetic resonance imaging (hMRI) of 12 symptomatic atherosclerotic middle cerebral artery (MCA), 3D fully coupled fluid-structure interaction (FSI) models were constructed to assess biomechanical behaviors of the vulnerability of MCA plaque.
METHOD AND MATERIALS

Twelve symptomatic patients with unilateral atherosclerotic stenosis of MCA who were prepared to be treated by interventional therapy (stent angioplasty and/or balloon dilatation) were enrolled in our study. Firstly, affected MCA was examined by hrMRI, and the geometric data were extracted from the wall images of hrMRI for constructing FSI models. Secondly, the flow rate and regional blood pressure proximal to the stenotic MCA were measured by phase-contrast MRI and invasive pressure probe of microcatheter. After a series of pre-processing steps of 3D reconstruction, shrink-stretch process and mesh generation process, the coupled FSI models were solved by a finite-element package ADINA. Finally, the plaque maximum primary stress (MPS) and maximum primary stretch ratio (STRETCH-P1) were extracted from 3D FSI solutions.

RESULTS

For the correlation analysis between mechanical and morphological data of MCA plaques, there were positive correlations between MPS and lumen area (the correlation coefficients was 0.4737 and P value was 0.0027); and the STRETCH-P1 and plaque burden (PB) was negative correlation (-0.3987, 0.0131). For different plaque component analyzing, MPS values were higher in plaque slices with 'lipid core' than those in plaque slices with 'fibrosis' components, despite the differences were no significant (P>0.05). Plaque slices with 'lipid core' suffered significant higher STRETCH-P1 than 'fibrosis' plaque slices (P=0.0169).

CONCLUSION

There were negative correlations between MPS/STRETCH-P1 and PB in symptomatic plaques of atherosclerotic middle cerebral artery, which indicate relatively big plaque suffered lower stress/strain burden. Moreover, plaque with 'lipid core' possessed higher MPS/STRETCH-P1 than 'fibrosis' plaque, which means lipid-rich plaque has relatively higher risk of rupture.

CLINICAL RELEVANCE/APPLICATION

Mechanical analysis may be complementary to luminal stenosis and plaque structure in determining clinical presentation in patients with MCA atherosclerotic disease. However, larger sample size studies and pathological control studies are required to further validate the results of this study.

SSA17-05 Advanced Atherosclerotic Disease with Intraplaque Hemorrhage is Present in Non-Stenotic Carotid Arteries of Diabetic Patients

Sunday, Nov. 29 11:25AM - 11:35AM Location: N227

Pascal N. Tyrrell, PhD, Toronto, ON (Abstract Co-Author) Nothing to Disclose
David Jenkins, Toronto, ON (Abstract Co-Author) Nothing to Disclose

PURPOSE

Diabetic patients have an increased risk of ischemic cerebrovascular events with worse outcomes than the non-diabetic population. Carotid artery stenosis currently stratifies patient risk but, even without significant stenosis, intraplaque hemorrhage (IPH) may predict cerebrovascular events. We report the prevalence of IPH in an asymptomatic diabetic population without carotid artery stenosis, using 3-dimensional (3D) magnetic resonance imaging (MRI) and investigate its association with carotid artery wall volume.

METHOD AND MATERIALS

Patients were recruited from a prospective dietary trial between 2010 and 2013, with a carotid intima-media thickness (IMT) >1.2mm and non-stenotic carotid arteries on ultrasound. All were asymptomatic type 2 diabetic patients who underwent baseline 3D T1-weighted black blood imaging for visualization of intraplaque hemorrhage (3D-MRIPH) and 3D-time of flight imaging. Carotid artery vessel wall (VW) volumes and IPH volumes were determined bilaterally for a standard 32 mm segment centered at each carotid bifurcation, using a validated approach with the software, VesselMASS (Medis, Netherlands). Descriptive statistics as well as repeated measures linear regression analyses were performed.

RESULTS

159 patients were included with mean age 63.1 ± 7.9 years, 62.3% male, 17.9% with a smoking history and 69.2% on hypertensive medication. The prevalence of IPH was 23.3% (n=37) with five patients exhibiting IPH in both carotid arteries. VW volume of the IPH positive carotid arteries was found to be significantly different from IPH negative arteries (β=0.15mm³ SE=0.03, p<0.01) and independent from other factors that affected VW volume - age (β=0.07yrs SE=0.002, p<0.01), sex (β=0.21 SE=0.04, p<0.01), BMI (β=0.22 SE=0.10, p=0.03) - when adjusted (none significant) for disease duration, smoking, blood pressure, and medications (statins, anti-hypertensive, anti-platelet).

CONCLUSION

IPH can be found in the absence of carotid artery stenosis in asymptomatic diabetic patients and is associated with an increased carotid artery wall volume as measured by 3D-MRI. It represents a biomarker of advanced atherosclerotic disease and may identify individuals at higher risk of cardiovascular disease.

CLINICAL RELEVANCE/APPLICATION

3D MRI can identify high risk cardio vascular biomarkers, such as intraplaque hemorrhage, in diabetic patients before onset of stenosis.

SSA17-06 Feasibility of High-resolution MR Imaging for the Diagnosis of Posterior Inferior Cerebellar Artery Dissection

Sunday, Nov. 29 11:35AM - 11:45AM Location: N227
PURPOSE
To evaluate the feasibility of HR-MR imaging diagnosing posterior inferior cerebellar artery (PICA) dissection and to find most useful imaging findings suggesting dissection.

METHOD AND MATERIALS
We retrospectively reviewed 104 patients suspected of having arterial dissection involving posterior cerebral circulation and underwent HR-MR imaging between March 2012 and March 2015. 66 patients were diagnosed with arterial dissection involving posterior cerebral circulation and 16 patients among them (24.2%) were diagnosed with isolated PICA dissection by the consensus among neuroradiologists, neurointerventionist and neurologist after reviewing all clinical and paraclinical investigations available at hospital discharge (initial CT, MR, DSA images and etiologic work-ups) and follow up. Two neuroradiologists independently reviewed the HR-MR images of patients finally diagnosed as PICA dissection and looked for evidence of dissection (mural hematoma, dissection flap, outer diameter enlargement on T2WI) on each sequence of HR-MRI (PDWI, T2WI, T1WI and CE-T1WI). Inter- and intraobserver agreement for detecting evidence of dissection was estimated using the Cohen's kappa coefficient.

RESULTS
Dissection flaps were seen in all cases on T2WI (100%) and secondly detected on CE-T1WI (81.3%). Outer-diameter enlargement of the steno-occlusive lesions on angiography was detected in most of cases (81.3%). A mural hematoma was best detected on CE-T1WI (50.0%). The two reviewers showed substantial to almost perfect agreement for detecting dissection signs on every sequence (Cohen's kappa coefficient: 0.63 ~0.94)

CONCLUSION
HR-MR imaging could be a useful and non-invasive diagnostic tool for PICA dissection and dissection flap with outer wall enlargement on T2WI is most confident sign for suggesting dissection.

CLINICAL RELEVANCE/APPLICATION
HR-MR imaging can demonstrate direct findings of dissection and be non-invasive useful diagnostic tool for the diagnosis of posterior inferior cerebellar artery dissection

SSA17-07 Correlation of Carotid Plaque Features with Acute Cerebral Infarction in Type 2 Diabetic Patients - A Magnetic Resonance Imaging Study

Sunday, Nov. 29 11:45AM - 11:55AM Location: N227

Participants
Beibei Sun, Shanghai, China (Presenter) Nothing to Disclose

PURPOSE
The aim of this study was to investigate the association between carotid atherosclerotic plaque characteristics and the severity of acute cerebral infarct (ACI) in symptomatic patients with T2DM.

METHOD AND MATERIALS
We studied 204 arteries in 102 stroke patients by carotid and brain MRI. ACI volume was determined from symptomatic internal carotid artery territory on diffusion-weighted imaging (DWI). The symptomatic carotid plaque burden and compositional characteristics between stroke patients with T2DM and without T2DM were compared by using independents sample t-test and nonparametric Wilcoxon signed rank test after analyzed with MR vessel imaging. Pearson correlation test was applied to determine the correlations between volume of ACIs and carotid features in T2DM patients, then univariate and multivariate linear regressions were applied to assess the independent associations of carotid characteristics with severity of ACIs.

RESULTS
Out of 104 enrolled stroke patients, 44(42%) had T2DM. They were distinguished as atherosclerotic plaque based on carotid artery with presence of any plaque component on MRI, such as calcification, LRNC, or IPH. The occurrence rate of carotid artery plaque was higher in diabetics vs non-diabetics (76.1% vs 52.6%, p=0.001). Compared with patients without T2DM, the T2DM subjects showed significantly higher prevalence of LRNC (70.5% vs 48.3%, P=0.038) as well as a larger volume of LRNC (76.82±114.31 mm³ vs 35.91±73.79mm³, P=0.042). Among these stroke patients, ACIs size of T2DM subjects in internal carotid artery (ICA) territory (7.75±11.49mm³ vs 3.77±6.33mm³, P=0.042) are greater than that of non-T2DM subjects. In addition, The LRNC volume had showing significantly higher prevalence of LRNC (70.5% vs 48.3%, P=0.038) as well as a larger volume of LRNC (76.82±114.31 mm³ vs 35.91±73.79mm³, P=0.042). Among these stroke patients, ACIs size of T2DM subjects in internal carotid artery (ICA) territory (7.75±11.49mm³ vs 3.77±6.33mm³, P=0.042) are greater than that of non-T2DM subjects. In addition, The LRNC volume had superior correlation (r=0.77, p<0.001) with the infarction volume of ipsilateral ICA territory, outperforming the other parameters in T2DM patients. Univariate and multivariate linear regression analysis showed close correlation of LRNC volume and MWT with the severity of ACI (B= 0.15, P=0.01 and B=4.99, P<0.05, respectively).

CONCLUSION
LRNC prevalence and volume of carotid plaques are significantly different between stroke patients with T2DM and without T2DM. In addition, LRNC volume and MWT are independently associated with cerebral infarction as measured by DWI.

CLINICAL RELEVANCE/APPLICATION
Our findings indicate that characterizing atherosclerotic plaque by MR vessel wall imaging might be useful for stratification of plaque risk and infarction severity in T2DM patients.

SSA17-08  Early Atherosclerotic Disease Detected by MRI and CT in the Carotid and Coronary Arteries in Low-moderate Risk Individuals

PURPOSE

We examined the relationship between positive remodeling in the carotid and coronary arteries and investigated determinants of remodeling in a population with low-moderate risk of cardiovascular disease.

METHOD AND MATERIALS

Study subjects >55 years old with history of hypercholesterolemia underwent high resolution black blood carotid MRI using dedicated surface coils at 3T. In addition, CT angiography was performed using 320 slice scanning. Arterial wall area (outer vessel area-lumen) and the remodelling index (RI) (wall area/outer vessel area) were measured by observers blinded to clinical status. Data were analyzed using Spearman’s correlation coefficient and multivariate linear regression analysis adjusted for sex, age, height and weight.

RESULTS

In 201 individuals (mean age 65.3±6.5, 64% men) with a low-moderate risk (Framingham Risk Score 7.8±7.6%), we found a strong association between wall area and outer vessel area in both the carotid (r=0.80; p<0.001, adjusted beta 1.67 [95%CI 1.43-1.92]) as well as the coronary arteries (r=0.82; p<0.001, adjusted beta 1.48 [95%CI 1.24-1.72]). This association was stronger when we compared the third tertile of lumen area to the first tertile, indicating more outward remodeling. The RI of the right and left carotid artery in a study subject was strongly correlated (r=0.75, p<0.001), whereas intra-individual RI between carotid and coronary disease was weak (r=0.20, p<0.001). In multivariate analysis, hypercholesterolemia, height and CAC score were associated with the RI of the coronary arteries.

CONCLUSION

This study is the first to combine MRI and CT imaging to investigate positive remodeling in the carotid and coronary arteries of low-moderate risk individuals from the general population. Early atherosclerosis was associated with positive remodeling with larger diameter in the coronary and carotid arteries. Positive remodeling was not the same for different vascular beds.

CLINICAL RELEVANCE/APPLICATION

Detection of positive remodeling and understanding its role in early atherosclerotic disease could improve prevention strategies and management of stroke and coronary heart disease.

SSA17-09  Characterization of Restenosis after Carotid Endarterectomy Using Contrast-Enhanced Black Blood MRI

PURPOSE

To characterize restenosis after carotid endarterectomy (CEA) using high-resolution contrast-enhanced black blood MRI (CEMRI) and compare with primary atherosclerotic lesions.

METHOD AND MATERIALS

17 consecutive patients (10 male; mean age 73.4±11.9 years) with carotid restenosis (13 unilateral; 4 bilateral) after CEA underwent CEMRI at 3T. The median interval between surgery and CEMRI was 16.5 months (IQR, 9.3-95.5 months). Patients were matched with 20 asymptomatic patients with primary carotid atherosclerosis (19 unilateral; 1 bilateral) by age and luminal stenosis. Patients who underwent CEMRI at 3T. The median interval between surgery and CEMRI was 16.5 months (IQR, 9.3-95.5 months). Patients were matched with 20 asymptomatic patients with primary carotid atherosclerosis (19 unilateral; 1 bilateral) by age and luminal stenosis. All MRI images were de-identified and interpreted by two readers who were blinded to the history of CEA. The presence of plaque and plaque components was recorded for each lesion based on previous criteria on CEMRI. The lesions were classified as plaques or intimal hyperplasia based on the presence/absence of plaque features on CEMRI. The MRI morphological measurements included wall thickness (WT), area, normalized wall index and eccentricity (maximum WT - minimum WT)/maximum WT), and the signal measurements included heterogeneity (defined by coefficient of variation of signal intensity) and contrast-enhancement (%CE, the
percent change in signal intensity from the pre- to post-contrast images).

RESULTS
A total of 42 carotid lesions from 37 patients were analyzed, and classified as primary plaques (n=21), recurrent plaques (n=13) and intimal hyperplasia lesions (n=8). Compared with plaques (both primary and recurrent), lesions with intimal hyperplasia exhibited smaller eccentricity (0.48 vs. 0.74, p<0.001), lower signal heterogeneity (20.0% vs. 27.2%, p=0.004) and higher % CE (88.4% vs 43.9%, p=0.002). Recurrent plaques had similar MRI characteristics when compared with primary plaques. However, recurrent lesions demonstrated higher CE (57.5% vs 35.4%, p=0.046) and more frequently involved in the medial wall of the internal carotid artery, an uncommon location for a plaque formation (recurrent vs. primary; 38.5% vs 4.8%, p<0.001).

CONCLUSION
Carotid restenosis from intimal hyperplasia demonstrated distinct imaging characteristics on CEMRI compared with atherosclerotic lesions.

CLINICAL RELEVANCE/APPLICATION
The phenotype of the restenotic lesions after CEA imposes different stroke risks. CEMRI imaging allows for the differentiation of these lesions and may provide insight into the treatment of restenosis.

**PURPOSE**

A recent study from a single large teaching hospital in 2014 suggested that the use of imaging in the emergency department (ED) may be decreasing. Our purpose was to study this issue on a nationwide basis.

**METHOD AND MATERIALS**

The national Medicare Part B Physician/Supplier Procedure Summary Master Files from 2001-2013 were evaluated. These files cover all patients in traditional Medicare fee-for-service (37.3 million in 2013). Volumes of radiography, CT, and noncardiac ultrasound (US) - the 3 major types of ED imaging - were determined by aggregating all CPT codes within each modality. Exams performed in EDs were determined by using Medicare's place-of-service codes. Utilization rates per 1000 Medicare beneficiaries were calculated. Medicare specialty codes were used to determine the specialty of the interpreting physicians.

**RESULTS**

The ED utilization rate per 1000 of radiography increased every year from 238 in 2001 to 323 in 2013 (+36%). In ED CT, the rate increased every year from 48 in 2001 to 158 in 2013 (+229%). The CT increase would have been even greater except for code bundling of CT scans of the abdomen and pelvis in 2011. In ED noncardiac US, the rate also increased every year from 8.6 in 2001 to 22.2 in 2013 (+158%). In 2013, radiologists interpreted 99% of ED radiographs and 99% of CT scans. They interpreted 88% of noncardiac US studies. The remaining US exams were interpreted by vascular surgeons (5%), ED physicians (3%), general surgeons (2%), or cardiologists (1%).

**CONCLUSION**

There has been a steady increase in the utilization rates of the 3 major types of imaging that are performed in ED patients. The increase has been quite sharp in CT and noncardiac US. Despite the recent report, there is no evidence that ED imaging use is declining. Radiologists strongly predominate in interpretation of all types of imaging in EDs, despite persistent efforts by some other specialties to gain a foothold.

**CLINICAL RELEVANCE/APPLICATION**

NA
Utility of Computed Tomography (CT) imaging has been well validated in the initial assessment of trauma patients. However, there are some patients who are deemed too unstable to undergo CT scan and initially require exploratory laparotomy. Occasionally additional injuries are identified on CT if performed after surgery; however, to our knowledge, there have been no studies investigating types and severity of such injuries. The purpose of this study was to determine the diagnostic yield and clinical utility of CT following emergent laparotomy in the setting of trauma.

METHOD AND MATERIALS

The trauma databases of two urban level 1 trauma centers were queried over a 5 year 8 month period for patients who underwent abdominal/pelvic CT imaging within 48 hours of emergent exploratory laparotomy. CT reports and images were retrospectively reviewed to identify all injuries diagnosed by post-laparotomy CT. All injuries diagnosed at laparotomy were identified by reviewing the operative records. Comparisons were made between operative and CT findings.

RESULTS

92 patients met inclusion criteria. 64 patients (69.6%) had additional injuries not identified during laparotomy. There were 20 unidentified solid organ injuries, including 4 splenic, 4 hepatic, and 7 renal injuries. CT upgraded severity of 4 liver injuries that were diagnosed at initial surgery. Of 16 patients with suspected renal injury at surgery, there were 12 renal injuries confirmed by CT. 11 patients (12.0%) had CT injuries severe enough to prompt further intervention, including 5 angiography/embolizations and 6 re-operations. Fractures were found in 59 (64%) patients.

CONCLUSION

Overall there was high concordance between injuries identified on CT and those which could reasonably be expected to be identified at surgery. In total, 70% of patients had undiagnosed injuries; however, some of these injuries, such as fractures, would not be expected to be diagnosed at surgery. 12% of patients had injuries on CT severe enough to require further intervention. Post laparotomy CT adds value in trauma patients who initially require emergent exploratory laparotomy.

CLINICAL RELEVANCE/APPLICATION

Post laparotomy CT identifies clinically important injuries in a small but significant percentage of trauma patients who require initial emergent exploratory laparotomy and is recommended for complete evaluation of traumatic injuries.

Duplicate Cardiothoracic Imaging in the ED: Is there Room for Improvement?

EXAMINE EMERGENCY DEPARTMENT (ED) ORDERING PRACTICES IN PATIENTS RECEIVING BOTH CHEST RADIOGRAPHY (CXR) AND CHEST COMPUTED TOMOGRAPHY (CCT).

METHOD AND MATERIALS

Consecutive ED patients receiving both CXR and CCT in a single ED visit from 6/2009-3/2013 were included. For each exam, time of order entry (TOE), time of study completion (TSC), and time of final interpretation (TOI) was recorded and analyzed. TOE was the time of electronic order entry by the ED provider. TSC was when images were uploaded to PACS. TOI was the time of final radiology report availability. Cases with incomplete data were excluded.

RESULTS

3627 patients (66.5% male, average age 49.2 ±36 years) met inclusion criteria. In 3437 (94.8%) patients the CXR was ordered first, in 43 (1.2%) the CXR was ordered first, and in 91 (2.5%) the CCT and the CXR were ordered simultaneously. Of the 91 patients with simultaneous CCT and CXR orders, the CXR was completed first in 78 cases (85.7%); none of the 91 patients had chart documentation to explain the simultaneous orders. In only 50.6% (1740/3437) of exams where CXR was ordered first, was the final CXR report available prior to CCT order placement. Of the 43 patients in whom CCT was ordered first, only 2 (4.6%) had the final CCT report available prior to the CXR order. In 47.8% (1735/3627) of all cases, the second imaging modality (whether CT or CXR) was ordered prior to final report availability of the first exam. In 7.3% (n=263/3627) of all cases, the second imaging modality (whether CT or CXR) was ordered prior to the image availability of the first exam.

CONCLUSION

Making secondary cardiothoracic imaging decisions without having the final radiology report for the primary exam (47.8% of all cases) or ordering a secondary cardiothoracic imaging study prior to image availability for the first exam (7.3%) may be appropriate in certain situations, but further investigation of these trends is needed to identify possible inappropriate resource utilization. In 2.5% of cases, CCT and CXR were ordered simultaneously, which may occur secondary to perceived wait times for CCT. Targeted technology solutions may alleviate some of this redundancy.

CLINICAL RELEVANCE/APPLICATION

Primary imaging results should influence secondary imaging decisions. Efficient imaging in the ED helps arrive at an accurate diagnosis while minimizing cost, radiation, and patient turn around time.

Radiological Workflow in Mass Casualty Incidents: Evaluation of Two Level 1 Trauma Sites in a Large-scale Exercise

PURPOSE

Examine Emergency Department (ED) ordering practices in patients receiving both chest radiography (CXR) and chest computed tomography (CCT).

METHOD AND MATERIALS

Consecutive ED patients receiving both CXR and CCT in a single ED visit from 6/2009-3/2013 were included. For each exam, time of order entry (TOE), time of study completion (TSC), and time of final interpretation (TOI) was recorded and analyzed. TOE was the time of electronic order entry by the ED provider. TSC was when images were uploaded to PACS. TOI was the time of final radiology report availability. Cases with incomplete data were excluded.

RESULTS

3627 patients (66.5% male, average age 49.2 ±36 years) met inclusion criteria. In 3437 (94.8%) patients the CXR was ordered first, in 43 (1.2%) the CCT was ordered first, and in 91 (2.5%) the CCT and the CXR were ordered simultaneously. Of the 91 patients with simultaneous CCT and CXR orders, the CXR was completed first in 78 cases (85.7%); none of the 91 patients had chart documentation to explain the simultaneous orders. In only 50.6% (1740/3437) of exams where CXR was ordered first, was the final CXR report available prior to CCT order placement. Of the 43 patients in whom CCT was ordered first, only 2 (4.6%) had the final CCT report available prior to the CXR order. In 47.8% (1735/3627) of all cases, the second imaging modality (whether CT or CXR) was ordered prior to final report availability of the first exam. In 7.3% (n=263/3627) of all cases, the second imaging modality (whether CT or CXR) was ordered prior to the image availability of the first exam.

CONCLUSION

Making secondary cardiothoracic imaging decisions without having the final radiology report for the primary exam (47.8% of all cases) or ordering a secondary cardiothoracic imaging study prior to image availability for the first exam (7.3%) may be appropriate in certain situations, but further investigation of these trends is needed to identify possible inappropriate resource utilization. In 2.5% of cases, CCT and CXR were ordered simultaneously, which may occur secondary to perceived wait times for CCT. Targeted technology solutions may alleviate some of this redundancy.

CLINICAL RELEVANCE/APPLICATION

Primary imaging results should influence secondary imaging decisions. Efficient imaging in the ED helps arrive at an accurate diagnosis while minimizing cost, radiation, and patient turn around time.
CONCLUSION

Facility design has a major influence on the time needed for in-house treatment. Short distances allow reaching end-points within 22 min. Considering CT it is possible to serve up to 6 patients per scanner-hour by using a standard protocol and up to a theoretical maximum of 13 patients by using a CT triage procedure.

CLINICAL RELEVANCE/APPLICATION

Considering polytrauma patients in CT, optimized facility design with short distances allows to serve up to 6 patients/h using a standard protocol, and up to a theoretical maximum of 13 patients/h by using a more simple triage procedure.

SSA05-06  Time to Write an Obituary? Sacrum and Coccyx Radiographs have Limited Clinical Impact in the Emergency Department

Sunday, Nov. 29 11:35AM - 11:45AM Location: N228

Participants

Mahniya Sadiq, BS, Atlanta, GA (Abstract Co-Author) Nothing to Disclose
Tarek N. Hanna, MD, Atlanta, GA (Abstract Co-Author) Nothing to Disclose
Abhijit Datir, MD, Atlanta, GA (Abstract Co-Author) Nothing to Disclose
Saurabh Rohatgi, MD, Atlanta, GA (Abstract Co-Author) Nothing to Disclose
Faisal Khosa, FFR(RCSI), FRCPC, Atlanta, GA (Abstract Co-Author) Nothing to Disclose
Marc D. Benayoun, MD, PhD, Atlanta, GA (Abstract Co-Author) Nothing to Disclose

PURPOSE

Determine the yield and clinical impact of sacrum and coccyx radiographs (SC-XR) in the Emergency Department (ED).

METHOD AND MATERIALS

Consecutive SC-XR obtained in the EDs of 4 hospitals over a 5 year period were categorized as positive for acute fracture or dislocation, negative, or other. Other documented incidental findings that may have clinical relevance. Five follow-up metrics were analyzed: follow-up imaging in the same ED visit, follow-up imaging within 30 days, new pain medication prescriptions at discharge, clinic follow-up recommended at discharge, and surgical intervention within 60 days.

RESULTS

687 patients met inclusion criteria (48.1 years, 61.6% female). 91.3% were negative, 8.4% (n=58/687) were positive, and 0.3% (n=2/687) had other findings (lytic metastatic disease, Paget’s). Regarding follow-up: 5.7% (n=39) had follow-up imaging in the same ED visit, 4.3% (n=29) had advanced imaging within 30 days, 65.8% of patients received recommendations for clinical follow-up, and 47.9% of patients were prescribed new pain medications. Due to inherent practice differences, the level 1 trauma center was analyzed separately. At the level 2 trauma centers (n=352, 51.3 years, 69.4% female), when comparing positive and negative SC-XRs, there was no significant difference in same day (p=0.04) and 30 day imaging follow-up (p=0.77), medication administration (0.06), or clinical follow-up (p=0.14). At the level 2 trauma centers (n=352, 51.3 years, 69.4% female) there was a significant difference in same day (p=0.04) and 30-day follow-up imaging (p=0.001), but no difference in pain medication (p=0.94) or clinic follow-up (p=0.09). 0% (0/58) of the positive cases had surgical intervention. At our institution, the average global charge for SC-XRs over the study period was $230 ($201-263), $24 professional and $206 technical, for a total cost over the study period of $158,010.

CONCLUSION

ED SC-XRs have costs and ionizing radiation, and in some EDs result in more advanced imaging. However, the results of SC-XR did not affect pain medication administration or clinic follow-up. No positive SC-XRs resulted in surgical intervention.

CLINICAL RELEVANCE/APPLICATION

ED SC-XRs have costs and ionizing radiation, and in some EDs result in more advanced imaging. However, the results of SC-XR did not affect pain medication administration or clinic follow-up. No positive SC-XRs resulted in surgical intervention.
As ED SC-XRs do not affect clinical management, their use can be curtailed, and patients treated conservatively. This will result in radiation and cost savings, and may decrease ED length of stay.

### SSA05-07  Incidental Findings in Patients with Multiple Injuries: How to Proceed?

**Sunday, Nov. 29 11:45AM - 11:55AM Location: N228**

**Participants**
- Thomas Lehnert, MD, Frankfurt Am Main, Germany (Abstract Co-Author) Nothing to Disclose
- Moritz H. Albrecht, MD, Frankfurt am Main, Germany (Presenter) Nothing to Disclose
- Julian L. Wichmann, MD, Charleston, SC (Abstract Co-Author) Nothing to Disclose
- Nour-Eldin A. Nour-Eldin, MD, PhD, Frankfurt Am Main, Germany (Abstract Co-Author) Nothing to Disclose
- Moritz Kaup, Frankfurt, Germany (Abstract Co-Author) Nothing to Disclose
- Jan-Erik Scholtz, MD, Frankfurt, Germany (Abstract Co-Author) Nothing to Disclose
- Thomas J. Vogl, MD, PhD, Frankfurt, Germany (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

Multislice computed tomography (MSCT) is the diagnostic criterion standard for the initial evaluation of patients with suspected multiple injuries. Besides scanning for injuries directly related to the initial trauma, MSCT scans can reveal pathologies unrelated to the trauma of clinical relevance. The aim of the present study was to determine the frequency and follow-up course of incidental findings in patients with multiple injuries.

**METHOD AND MATERIALS**

This is a retrospective analysis of prospectively collected data on 2,242 patients with suspected multiple injuries at a Level I trauma center from 2006 to 2010. The MSCT reports were retrospectively reviewed regarding abnormal findings not related to trauma. These incidental findings were classified on a four-point level scoring system with respect to clinical importance and urgency for further diagnostic and therapeutic procedures.

**RESULTS**

During initial trauma center evaluation in the emergency department, 2,246 patients met our inclusion criteria. A total of 2,036 patients (90.7%) underwent MSCT; 1,142 (50.9%) of the patients had one or more incidental findings. A total of 2,844 incidental findings were detected. Overall, 349 tumor findings were noted (12.3% of all incidental findings); 113 findings were suspicious for malignant processes or metastasis. According to our classification, 168 (5.9%) of the incidental findings required urgent follow-up (Level 4), and 527 (18.5%) of the incidental findings required a follow-up before discharge (Level 3).

**CONCLUSION**

MSCT in patients with multiple injuries reveals one or more incidental findings in more than one of two patients. A scoring system classifying for relevance of incidental findings was introduced and could be applied in routine trauma care in the future.

**CLINICAL RELEVANCE/APPLICATION**

The consequent handling of incidental findings may add an extra burden for trauma surgeons and emergency physicians but should lead to improvements in health care for the patients. Especially in trauma patients, the reviewing radiologist should pay attention to both the presence of traumatic injuries and the incidental findings and communicate both to the ordering physician.

### SSA05-08  Completion CT Chest Abdomen Pelvis after Acute Head and Neck Trauma: Incidence of Acute Traumatic Pathology

**Sunday, Nov. 29 11:55AM - 12:05PM Location: N228**

**Participants**
- Michael S. Kelleher Jr, MD, New Haven, CT (Presenter) Nothing to Disclose
- Guangzu Gao, MD, New Haven, CT (Abstract Co-Author) Nothing to Disclose
- Michael F. Rolen, MD, New Haven, CT (Abstract Co-Author) Nothing to Disclose
- Syed A. Bokhari, MD, New Haven, CT (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

At our institution, patients found to have acute head or neck trauma will receive a CT chest abdomen pelvis (CT CAP) even in the absence of signs or symptoms to suggest bodily trauma. The purpose of our study was to determine the incidence of acute traumatic pathology on these CT CAP exams.

**METHOD AND MATERIALS**

After receiving IRB approval, a retrospective chart review was performed. Patients who presented to our institution’s emergency department over a one-year period (8/1/2013-7/31/2014) with findings of acute head and neck trauma who subsequently went on to have a CT CAP were identified. Exclusion criteria were as follows: proximal extremity/rib fractures identified on plain film prior to CT CAP, chest pain, abdominal pain, CPR after the traumatic event, soft tissue hematomas identified on physical exam and hypotension. We then analyzed the clinical course and imaging results of each patient meeting study criteria. Specifically, for the head/neck CTs, type of injury was divided into 5 broad categories: intra-axial bleed, extra-axial bleed, facial bone fracture, skull fracture, and cervical spine fracture. Mechanism of injury was categorized as follows: fall from standing, fall from height (greater than 6 feet), motor vehicle collision, and assault. The frequency and percentage of each of these categories were calculated. For the CT CAP exams, acute traumatic injuries were recorded, and the incidence of acute traumatic injury was calculated.

**RESULTS**

101 (8.6%) CT CAP studies performed in our ED during the one-year period met study criteria. The most frequent mechanism of injury in this group was a fall from standing (76.2%). The most common traumatic head/neck injury in this group was an extra-axial hemorrhage (49.5%). Of all CT CAP studies, only one study demonstrated an acute traumatic injury (non-displaced 5th and 6th rib fractures). This finding was of no significant clinical consequence.
CONCLUSION

In the setting of low-velocity trauma, patients with acute head/neck injury without signs or symptoms of bodily injury should not receive a CT CAP. This data can be used to restructure trauma algorithms, which will reduce financial costs and better utilize radiological resources in the emergency department setting.

CLINICAL RELEVANCE/APPLICATION

CT CAP is an unnecessary exam for low-velocity trauma patients with acute head/neck injury in the absence of signs or symptoms to suggest bodily injury.

SSA05-09 Effect of Timing of Request on Imaging Approach to the Diagnosis of Acute Appendicitis in a Group of Teaching Hospitals with 24/7 Availability of Ultrasound Technologist

Sunday, Nov. 29 12:05PM - 12:15PM Location: N228

Participants
Mostafa Atri, MD, Toronto, ON (Abstract Co-Author) Nothing to Disclose
Hassan Al Zahrani, Toronto, ON (Presenter) Nothing to Disclose
Ravi Menezes, PhD, Toronto, ON (Abstract Co-Author) Nothing to Disclose

PURPOSE

To determine if time of the day and day of the week influence the type of imaging request to evaluate for acute appendicitis and the performance of different modalities during and after regular hours.

METHOD AND MATERIALS

This is an REB approved retrospective study of consecutive patients operated with pre-operative diagnosis of acute appendicitis between Feb 2013 and August 2014 in three teaching hospitals with 24/7 US technologist coverage. Acquisition of consent was waived. Data collected included: a) the rate of US only, CT only and US followed by CT performed between 8AM and 5PM during the regular hours and after this period during the week, and weekend and holidays, and b) performance of each imaging approach. US examinations were all initiated by a technologist and reviewed by a staff/fellow during regular hours and by a resident/fellow after hour.

RESULTS

Three hundred and thirty seven patients were operated during this period. They included 152 women and 185 men, ranging in age from 18 to 85 (mean 36±15) years old. One hundred thirteen (33.5%) of patients were imaged before and 224 (66.5%) after regular hour (p=0.001). Eighteen (5.3%) had negative appendectomy, 5 (4.4%) during regular hour and 13 (5.8%) after hour (p>0.05), and 319 patients had appendicitis or a condition of appendix requiring surgery. Regular hour imaging included 59 (52%) US only, 32 (28%) CT only, and 22 (20%) US followed by CT. The corresponding numbers for after-hour examinations were 109 (48%), 98 (44%), and 22 (20%) (p =0.006). Sensitivity of US during regular hour was 72% (56/78), and CT was 76% (40/53). The corresponding sensitivities for after hour examinations were 86% (101/118) (p=0.018) and 95% (106/111) (p<0.001).

CONCLUSION

In spite of comparable sensitivity of US to CT, significantly higher number of CTs was requested after regular hour to evaluate for acute appendicitis.

CLINICAL RELEVANCE/APPLICATION

There are more CTs performed after regular hour to evaluate for acute appendicitis because of the wrong perception of lower accuracy of US being performed after regular hour.

PURPOSE
To investigate CT Angiographic (CTA) imaging capabilities of a whole-body prototype photon counting CT scanner in a large animal model, in comparison to 2nd generation dual-source dual energy CTA imaging.

METHOD AND MATERIALS
The prototype, whole-body photon counting CT (PCCT) scanner (Siemens Healthcare, Forchheim, Germany) is built on a Definition Flash dual-source platform, where the "A" detector/source sub-system uses a conventional energy-integrating detector (EID) and the "B" detector/source sub-system uses a photon-counting detector (PCD). Six pigs were imaged at clinically equivalent doses on the PCCT scanner (140 kV, 140 mAs, 15.51 mGy, 0.5 second rotation, 0.6 pitch, 32x0.5 collimation) and a commercial dual-source CT system (Definition Flash, Siemens Healthcare) (80/Sn140kV, 406/157 mAs, 15.4 CTDIvol, 0.5 second rotation, 0.5 pitch, 32x0.6 collimation). Energy spectrum thresholding on the PCCT scanner was set for 25 keV and 65 keV, resulting in two threshold (25-140 keV and 65-140keV) and two bin (25-65keV and 65-140keV) image datasets. CT angiograms of the head and neck, thorax, and abdomen/pelvis were obtained on both systems (100 ml Iohexol 350 Injection + 35 ml saline chaser). Images were reconstructed using the same clinical parameters (3.0 mm slices / 2.0 mm increment, D30f kernel) and qualitatively evaluated for general image quality and the presence of artifacts. Material decomposition was performed using an in-house developed material decomposition algorithm.

RESULTS
PCD images demonstrated decreased beam hardening relative to EID images and minimal ring, cupping or streaking artifacts. Qualitatively, CTA results were judged to be equivalent. Initial material decomposition results demonstrated good sensitivity to iodine and calcium separation.

CONCLUSION
The evaluated prototype whole-body PCD CT system was capable of producing clinical image quality CT angiographic exams with reduced artifacts and improved beam hardening.

CLINICAL RELEVANCE/APPLICATION
Whole-body CTA can be obtained with a whole-body photon counting CT scanner, using a single x-ray source while retaining the energy separation of a dual-source CT system with optimized filtration.

SSA19-02 Dose Efficiency of a Prototype, Whole-body, Photon-counting CT System versus a Conventional CT System for Imaging of Iodinated Contrast Media

Spectral Imaging on a 160 mm Clinical CT System with Fast kVp Switching: Evaluation of Image Quality

Sunday, Nov. 29 11:05AM - 11:15AM Location: S403B

Participants
Debashish Pal, PhD, Waukesha, WI (Presenter) Employee, General Electric Company
Kevin Mulligan, BEng, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Roman Melnyk, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Yasuhiro Imai, MS, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Jean-Baptiste Thibault, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Jiahua Fan, PhD, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company

Purpose:
Wide-cone CT systems with 160 mm aperture or more have several clinical benefits such as single shot cardiac imaging and helical scans with faster acquisition. Spectral imaging using fast kVp switching on such a system can additionally enable quantitative imaging and access to CT images at lower energies. The purpose of this work is to evaluate the new prototype image generation chain of a 160 mm spectral imager using fast kVp switching (Revolution CT, GE Healthcare, Waukesha, WI).

Method and Materials
The new spectral image generation chain incorporates an advanced model of the acquisition physics and measurement noise. It also builds upon the hardware advancements made in the wide-cone CT system and an advanced spectral modeling and projection-domain material decomposition (MD). A 33 cm Gammex phantom is scanned at three different dose levels (20.1, 11.9, 23.1 mGy) with known density of iodine. A 20 cm Gammex phantom is also scanned under 20.1 mGy. The MD (Water-Iodine) images are reconstructed using a slice thickness of 0.625 mm. The monochromatic images are generated from 40 - 140 keV. First noise in the monochromatic images at 0.625 mm slice thickness is measured by averaging across 3 different ROIs. Contrast to noise ratio (CNR) is also measured across all keVs at 0.625 mm slice thickness by placing a ROI on the 20 mg/cc iodine rod. Circular ROIs of radius 10 mm are placed on 5 mm averaged slices for measuring the mean density in the 5, 10, and 20 mg/cc iodine rods.

Results
The image chain is evaluated on Gammex phantoms with different size and dose level. The CNR monotonically increases from 140 to 40 keV for both 20 and 33 cm Gammex. The density accuracy of iodine is within 5% of the known density for all rods. The noise reduction at 40 and 140 keV for the 33 cm Gammex is measured to be 59% and 63% relative to MD images with no noise reduction. The noise reduction for the 20 cm Gammex at 40 and 140 keV is 58% and 61%.

Conclusion
The phantom study demonstrates superior image on both material and monochromatic images with the new image chain. Significant improvement in CNR is achieved at lower energies without compromising on the density accuracy.

Clinical Relevance/Application
The quantitative aspect of spectral imaging using the new imaging chain and improved contrast-to-noise at lower energies is
SSA19-04  Segmentation-Assisted Material Decomposition in Dual Energy Computed Tomography (DECT)

Participants
Stefan Kuchenbecker, MENG, Heidelberg, Germany (Presenter) Nothing to Disclose
Sebastian Faby, DIPLOPHYS, Heidelberg, Germany (Abstract Co-Author) Nothing to Disclose
David Simons, MD, Heidelberg, Germany (Abstract Co-Author) Nothing to Disclose
Michael Knap, PhD, Heidelberg, Germany (Abstract Co-Author) Nothing to Disclose

Marc Kachelries, PhD, Heidelberg, Germany (Abstract Co-Author) Nothing to Disclose

PURPOSE
Prior knowledge is required to decompose DECT data into more than two basis materials. Published methods show limitations regarding the assumptions made: The basis materials chosen often do not correspond to the anatomical structures (e.g. contrast agent represents bone, adipose tissue contains air, ...). Our purpose is to improve the prior knowledge to avoid misclassifications. In cases where ambiguities cannot be avoided we want to present them to the reader of the decomposed images.

METHOD AND MATERIALS
A common approach of DE-based three material decomposition can be visualized by a triangle in a DECT-diagram. The number of basis materials can be increased by using many triangles to tesselate the DECT-diagram into a mix of basis materials like air, blood, bone, contrast agent, fat, liver, etc. In contrast to other methods attempting such multi material decompositions we first segment and classify the anatomical structures shown in the DECT data set into the region types air, fatty tissue, soft tissue, (dense and) bone. Heuristics then choose the basis material triple (triangle vertices) that should be used for each region type among the set of the following basis materials: air, adipose tissue, liver tissue, contrast agent (CA), and calcium hydroxyapatite (CaHA). ROIs can be placed to quantify the contents. If an ROI contains no bone type region the decomposition into CaHA is omitted. In bone regions Ca is not quantified. ROIs containing bone together with tissue the tissue evaluation is ambiguous-it may represent organs, connective tissue or bone marrow. Therefore CaHA and CA are quantified simultaneously. Our approach was tested on simulations and on patient data acquired with a dual source CT system.

RESULTS
Due to segmentation of a patient data set the CaHA content inside a rib is determined (c~106 mg/mL) independently of the iodine content in neighboring soft tissue of CA (c=0.8 mg/mL). Segmented tissue is ambiguous-iodine c=0.4 mg/mL and CaHA c=17 mg/mL are evaluated. Representative adipose and liver tissue content are always assessed.

CONCLUSION
Our approach quantifies multiple materials according to the anatomical regions they belong to. No manual segmentation is required at improved accuracy to previous methods.

CLINICAL RELEVANCE/APPLICATION
The improved material quantification is important for diagnostics, e.g. to evaluate the vascularization of tumors or for CT-based bone mineral density analysis.

SSA19-05  Volumetric Fast kV Switching Development on Wider Cone Geometry System

PURPOSE
The purpose of this work is to evaluate the clinical feasibility of using a wider cone beam geometry system for volumetric fast kV switching imaging. With a detector width of 160-mm and fast helical pitch capability, spectral (dual-energy) scanning of larger volume coverages can be acquired faster with reduced motion artifacts but no increase in overall dose.

METHOD AND MATERIALS
Spectral imaging evaluation was done on a 160-mm wide cone clinical CT system with Fast kVp switching (Revolution CT, GE Healthcare, Waukesha, WI). Generator improvements allow for 3x faster switching performance between low and high kV. The 3D collimator and advanced detector design help reduce X-ray scatter and electronic noise, respectively, in the dual-energy images. Advanced spectral modeling, projection-based material decomposition, and advanced noise modeling have also been developed for spectral imaging. System evaluation was done by acquiring dual-energy scans across different dose levels at 40, 80, and 160-mm scan coverages. Phenoms used include: 20-cm and 33-cm dual-energy phantom with varying Iodine densities from 2.5mg/cc to 20mg/cc (Gammex, Inc., Middleton, WI), 20-cm water-filled phantom and custom-made 24.5-cm water-filled phantom with three 5-cm liquid iodine rods submerged. CT Hounsfeld Unit (HU) and Material Density (MD) Mean, standard deviation, and uniformity were measured across different monochromatic kV and MD volume images.

RESULTS
160-mm scans were acquired using 80/140 protocols as low as 3mGy. The 3x faster switching performance between kVps increased energy separation by 20%. With hardware improvements, measured CT HU and MD values for different iodine concentrations in the monochromatic keV and MD images were within 2% across all dose levels. MD values in the iodine and water material images were accurate within 6% and 2%, respectively. Due to modeling of the Heel Effect in the Advanced Spectral algorithm, increased uniformity was observed at wider scan coverages.

CONCLUSION

With advanced hardware and image processing improvements, system and phantom evaluation has shown that dual-energy imaging can be achieved on a wide coverage CT system using fast kV switching technology.

CLINICAL RELEVANCE/APPLICATION

Benefits of spectral imaging (i.e. reduced beam hardening artifacts, improved CNR over single kVp, material information) can be achieved for wider coverage scanning with minimal impact to overall image quality and dose.

SSA19-06 Reliability of the Iodine Signal in Dual-energy CT on Two Scanner Types: A Phantom Study Featuring Beam Hardening

Sunday, Nov. 29 11:35AM - 11:45AM Location: S403B

Participants

Johan De Mey, Jette, Belgium (Abstract Co-Author) Nothing to Disclose
Nico Buls, Dsc, PhD, Jette, Belgium (Abstract Co-Author) Nothing to Disclose

PURPOSE

A dual-energy (DE) phantom study was performed on two scanner types in order to evaluate (1) the stability and accuracy of CT numbers and iodine concentrations in function of object size; (2) the effect of beam hardening.

METHOD AND MATERIALS

Iodine concentrations of 3 and 6 mgI/ml were poured into two respective rows of cylindrical cavities with diameters ranging from 3 to 25.5 mm in an AAPM CT performance phantom. Besides this, a 16 mm diameter tube filled with 6 mgI/ml was placed in the main water-filled compartment, partly covered by a Teflon beam hardening ring. The phantom was scanned in standard 120 kVp and DE mode on a GE Healthcare Discovery HD750 and Siemens SOMATOM Definition Flash scanner at 3 CTDIvol's (9, 19 and 29 mGy).

Iodine concentrations were determined for all cavities using the scanner's DE mode, and compared to their true concentrations. CT number stability was determined accordingly and a comparison was made between the DE acquisition and standard 120 kV scanning.

RESULTS

(1) Relatively constant (max VAR 14%) HU values for both scanners as a function of the object diameters were observed. The Siemens scanner showed a consistent overestimate of approximately 0.5 mgI/ml for both contrast concentrations. A significant decrease in concentration accuracy for object diameters smaller than 6 mm was present for both scanners. (2) A step-like increase of 10 HU upon transitioning out of the Teflon part was observed for both scanners at single energy 120 kV and the Siemens blended DE image, less for the GE DE image (AV 148 HU, max VAR 5 HU).

CONCLUSION

(1) Measured and true iodine concentrations were consistent down to 6 mm object size, notwithstanding an observed offset with one scanner type. (2) A step-like increase in HU highlights the effect of beam hardening, and is more prominent for classical scans compared to DE.

CLINICAL RELEVANCE/APPLICATION

DE CT techniques are being increasingly used in tumor imaging. Since iodine is a contrast agent commonly used in CT imaging, determining its detectable lower limit is a crucial factor. Iodine concentration estimations should be made with appropriate consideration.

SSA19-07 Comparison of the Accuracy of Iodine Quantification with a Novel Split Filter Single-source Dual-energy CT Technique and a Second Generation Dual-source Dual-energy CT

Sunday, Nov. 29 11:45AM - 11:55AM Location: S403B

Participants
Andre Euler, MD, Basel, Switzerland (Presenter) Nothing to Disclose
Anushri Parakh, MBBS,MD, Basel, Switzerland (Abstract Co-Author) Nothing to Disclose

Sebastian T. Schindera, MD, Basel, Switzerland (Abstract Co-Author) Research Grant, Siemens AG; Research Grant, Ulrich GmbH & Co KG; Research Grant, Bayer AG

PURPOSE

To evaluate the accuracy of iodine quantification with a novel dual-energy technique on a single-source CT scanner using a split filter (TwinBeam Dual-Energy, Siemens) compared with dual-source dual-energy and single-source dual-spiral mode in a phantom.

RESULTS

The error of measurement for the iodine quantification ranged for the simulated intermediate-sized patient from 0.1 - 2.5 mgI/ml for
protocol A, from 0 to 6.9 mg/ml for protocol B and from 0.1 - 2 mg/ml for protocol C. For the simulated large patient, the error ranged from 0.6 - 7.1 mg/ml for protocol A, from 0.2 - 7.4 mg/ml for protocol B and from 0.3 - 3.3 mg/ml for protocol C.

CONCLUSION
The novel single-source dual-energy CT technique with a split filter offers comparable accuracy for iodine quantification to a second generation dual-source CT scanner in a simulated intermediate-sized patient. However in simulated large patients, greater measurement errors have to be expected with the single-source dual-energy technique.

CLINICAL RELEVANCE/APPLICATION
Accurate iodine quantification with the novel split filter dual-energy CT technique offers the possibility to eliminate additional CT examination or phases (e.g. assessment of iodine uptake of a renal lesion).

SSA19-08 Feasibility of a Basis Material Decomposition Using a Prototype Whole-Body Photon-Counting-based CT System and a Living Swine Model

Cynthia H. McCollough, PhD, Rochester, MN (Abstract Co-Author) Research Grant, Siemens AG

PURPOSE
The aim of this study was to evaluate the feasibility of performing in-vivo basis material decomposition at clinical dose levels using a prototype, whole-body photon counting CT scanner.

METHOD AND MATERIALS
A prototype, whole-body photon-counting CT (PCCT) scanner (Siemens Healthcare, Forchheim, Germany) was used in this study. After institutional animal care and use committee approval, six 3-month-old female swine were imaged at clinical doses (140 kV, 140/270 mAs, 0.5-1 second rotation time, 0.6 pitch, 32x0.5 collimation, and CTDIvol of 15.51/29.69 mGy) and full dose (440mAs, CTDIvol 68.44 mGy). The data were acquired using the "chess mode", with energy thresholds of 25, 45, 65, and 85 keV, where data from all 16 sub-pixels of the detector were combined to simultaneously generate 7 measurements at different X-ray energies. CT angiograms were obtained and images were reconstructed using clinical parameters (3.0 mm slices / 2.0 mm increment, D30f kernel). Phantom experiments were performed separately to evaluate the accuracy of our in-house developed material decomposition technique and generate the calibration data for the material decomposition of the in-vivo swine images. Noise reduction was applied on all 7 sets of PCCT images, prior to the implementation of the material decomposition algorithm, which resulted in 3 material specific images.

RESULTS
Phantom experiments showed good estimation of basis material densities with RMSE of 5.1, 0.9, 5.4 mg/ml (percent error: 3.6%, 6.6% and 0.3%) for calcium, iodine, and water, respectively at full dose. At the clinical dose level, the RSME values were 7.6, 1.2, and 9.0 mg/ml (percent error: 7.0%, 6.7% and 0.4%), respectively. Initial material decomposition results in living swine images demonstrated good separation and quantification of iodine, calcium, and water. The material decomposition performed robustly at clinical relevant dose levels when effective noise reduction was applied.

CONCLUSION
The evaluated prototype whole-body PCCT system demonstrated the potential for performing accurate basis material decomposition in-vivo at clinically relevant dose levels.

CLINICAL RELEVANCE/APPLICATION
Reliable material decomposition by the whole-body PCCT system under clinical dose level may be translated to clinical applications such as iodine quantification and stone characterization.

SSA19-09 Evaluation of Three-Stage Metal Artifact Reduction Software for 256-slice Fast-kV Switching Spectral CT

Participants
Kriti Sen Sharma, PhD,BEng, Woburn, MA (Abstract Co-Author) Employee, General Electric Company
Debashish Pal, PhD, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Taisuke Takemasa, Hino-Shi, Japan (Abstract Co-Author) Employee, General Electric Company
Roy A. Nilsen, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Jiang Hsieh, PhD, Waukesha, WI (Abstract Co-Author) Employee, General Electric Company
Elizabeth Nett, Waukesha, WI (Presenter) Employee, General Electric Company

PURPOSE
The purpose of this work is to evaluate the image quality of a prototype metal artifact reduction (MAR) algorithm for severe metal cases on a prototype fast-kV switching spectral CT scanner with wide-cone capability (Revolution CT, GE Healthcare, Waukesha, WI).

METHOD AND MATERIALS
A three-stage projection based metal artifact reduction algorithm (SmartMAR, GE Healthcare) originally designed for single energy...
A three-stage projection based metal artifact reduction algorithm (SmartMAR, GE Healthcare) originally designed for single energy CT is extended to spectral CT. The algorithm is developed to further improve the quantitative aspect of spectral imaging in the presence of dense metal objects such as hip implants, dental fillings. Two phantoms with metal inserts of various sizes were constructed: (1.) Titanium and Stainless Steel rods in water cylinders (Fig. A), (2.) torso phantom fitted with metal implants at extremities (Fig. C, D). The phantoms were scanned on a prototype fast-kV switching spectral CT scanner under the following protocol (80/140 kVp, 400 to 500 mAs). Scan-data was reconstructed without (baseline-recon) and with the new MAR algorithm. Three ROIs were placed at different locations in the phantoms as shown in Figs. A, D (two in area of high metal streak, and one away from metal). Noise performance was quantified for the two phantoms by calculating the average standard deviation $s_1$, $s_2$, and $s_3$ in selected ROI-s across all the slices affected by metal.

**RESULTS**

Images reconstructed with MAR (Figs. B, E) showed reduced beam hardening and streaks compared to baseline-recons (Figs. A, C, D). In area of metal streaks, the noise performance was improved for MAR recon ($s_1 : 15.25$, $s_2 : 25.28$) compared to baseline recon ($s_1 : 42.05$, $s_2 : 97.99$), i.e. a reduction of 63%, and 74% respectively). In areas away from metal, the standard deviation $s_3$ was reduced from 29.84 (baseline) to 17.54 (MAR), i.e. an improvement of 41%.

**CONCLUSION**

For severe metal cases, a prototype three-stage MAR algorithm for projection-based spectral CT showed improvements over baseline-recon in terms of image quality and noise performance.

**CLINICAL RELEVANCE/APPLICATION**

Projection based spectral CT allows native reduction of beam hardening artifacts arising from metallic objects; MAR processing further improves the quantitation by reducing residual artifacts caused due to factors such as photon starvation and partial volume.

Realistic Simulation of X-ray Phase-contrast Imaging at a Human Scale

Participants
Andrew Karellas, PhD, Worcester, MA (*Moderator*) Research collaboration, Koning Corporation  
Ernest J. Feleppa, PhD, New York, NY (*Moderator*) Research collaboration, General Electric Company; Research collaboration, SonaCare Medical, LLC

**PURPOSE**

X-ray phase-contrast imaging (XPCI) can dramatically improve soft tissue contrast in medical imaging. Despite worldwide efforts to develop novel XPCI systems, a numerical framework to rigorously predict the performance of a clinical XPCI system at a human scale is not yet available.

**METHOD AND MATERIALS**

We have developed a novel method of propagating the X-rays through a human-scale 3-D object [1]. Specifically, we have adopted the wave equation simplified with the first-order Rytov approximation, which allows us to quickly and accurately generate simulated amplitude and phase images that an XPCI detector would see. For our numerical phantom, we have adopted the XCAT model as defined with non-uniform rational B-splines (NURBS) [2]. Existing methods using the XCAT rely on ray tracing or Monte-Carlo simulation, which produce inaccurate XPCI simulations. Using our wave-based approach, we can accurately simulate the phase-contrast signal from the NURBS phantom.

**RESULTS**

Using the developed method, we have generated a projection image of a human chest for the grating-based method, the most popular XPCI method (Figure 1b). Compared to the attenuation image (Figure 1a), there is higher contrast between soft-tissue structures on the phase-contrast image. For example, all the structures obscured by the diaphragmatic silhouette are much better appreciated in the phase image. Similarly, the intra-vertebral disks are seen with greater clarity in phase-contrast than in attenuation. The phase-contrast image also demonstrates the bronchial tree (including the primary, secondary, and tertiary branches) better than the attenuation image.

**CONCLUSION**

Combining the NURBS-based XCAT phantom and our wave propagation simulator, we could simulate various XPCI methods at a full adult human scale, for the first time with the best of our knowledge.

**CLINICAL RELEVANCE/APPLICATION**

There is currently no XPCI system that can image a human torso. Our numerical tool can be used to predict and compare the performance of new XPCI systems on various disease entities in a clinical scenario.

control or image quality benchmarking of BT systems.

The proposed phantom enables the detection performance evaluation of BT against DM during acceptance testing, routine quality

**CLINICAL RELEVANCE/APPLICATION**

the detection of microcalcifications.

comparable to published clinical findings: BT performed better for the detection of masses, while both modalities were equivalent for

**CONCLUSION**

For patients with hepatic fibrosis caused by chronic hepatitis B, good diagnostic performance is shown for MFI parameter of P/A to
detect ≥F1 and ≥F2, but the distinguishment between stage F3 and F4 is difficult.

**CLINICAL RELEVANCE/APPLICATION**

Good diagnostic performance is shown for MFI parameter-P/A to detect ≥F1 and ≥F2 in patients with hepatic fibrosis.

**RESULTS**

A stepwise decrease with increasing histological hepatic fibrosis stage was observed for the parameters of Lmean and P/A, while a

Provider operator characteristic curve was performed to evaluate the diagnosis performance of MFI parameter for fibrosis

**METHOD AND MATERIALS**

The phantom consists of a 48 mm thick breast-shaped acrylic container, filled with water and acrylic spheres of different diameters.

Three-dimensionally printed spiculated (diameter range: 3.8-9.7 mm) and non-spiculated (1.6-6.2 mm) masses as well as

microcalcifications (90-250 µm) were inserted as targets. The phantom was imaged ten times in both DM and BT mode on four

systems: Siemens Inspiration, Hologic Selenia Dimensions, GE SonoClaire 3D and Fuji Amulet Innovality under automatic exposure

control. Five readers evaluated target detectability in a four-alternative forced-choice study. The percentage of correct responses

(PC) was assessed based on 10 trials of each reader for each object type, size and imaging modality. Additionally, detection

threshold diameters at 62.5% PC were assessed via fitting of the psychometric curve.

**RESULTS**

For microcalcifications, average PC was comparable for the four systems in DM and BT mode, ranging from 78% to 84% for DM and

from 64% to 82% for BT. Threshold diameters for microcalcification detection for the four systems ranged between 111 and 118 µm

in DM and between 113 and 158 µm in BT. For masses, PC values were higher in BT compared to DM. In DM, they ranged from 60%

to 75% for spiculated and from 31% to 45% for non-spiculated masses. For BT, detection of spiculated masses was the highest

(94% to 99%) and remained high for non-spiculated masses (65% to 85%). For spiculated masses threshold diameters were

between 4.6 and 6.3 mm for DM and between 1.7 and 2.6 mm for BT. Threshold diameters for non-spiculated masses lay outside

the range available in the phantom in DM mode while for BT threshold diameters were found between 1.8 and 3.1 mm.

**CONCLUSION**

The phantom was able to show detectability differences between DM and BT for four commercial systems. These results are

comparable to published clinical findings: BT performed better for the detection of masses, while both modalities were equivalent for

the detection of microcalcifications.

**CLINICAL RELEVANCE/APPLICATION**

The proposed phantom enables the detection performance evaluation of BT against DM during acceptance testing, routine quality

control or image quality benchmarking of BT systems.

**SSA20-04 VHF-Induced Thermoacoustic Imaging Using a Clinical Ultrasound Transducer Array**

Sunday, Nov. 29 11:15AM - 11:25AM Location: S404AB

Participants:

Sarah K. Patch, PhD, Milwaukee, WI (Presenter) Nothing to Disclose

William See, MD, Milwaukee, WI (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To demonstrate that a clinical ultrasound transducer array can detect VHF-induced thermoacoustic pulses with sufficient
A 96-channel transducer array (P4-1) providing 3 cm coverage was incorporated into a benchtop thermoacoustic imaging system for imaging fresh surgical specimens. Thermoacoustic signal was generated by 700 ns irradiation pulses with 11 kV/m electric field strength. Data was acquired simultaneously in step-and-shoot mode by the array and a 2.25 MHz focused single-element transducer. In-plane resolution and contrast were measured by imaging an 80-micron wire and a homogeneous cylindrical phantom. Several fresh human prostates were imaged immediately after surgery. Two sets of sinograms were acquired, separated by a 2 cm translation along the tomographic axis. The P4-1 data was reconstructed over a 6 x 6 x 5 cm³ volume. Rudimentary comparison to histology was performed.

RESULTS

As expected, the larger single element transducer was more sensitive and required 8-fold less signal averaging than the P4-1 array. Although nominal bandwidths of the P4-1 array and 2.25 MHz transducer are comparable, the single element transducer was more sensitive to low frequencies and provided better contrast, whereas the higher frequency P4-1 array provided better resolution. Full width at half maximum in the P4-1 and single element images of the 80-micron wire at isocenter were smaller and greater than 1 mm, respectively. CNR in the single element and P4-1 images of the cylindrical phantom were greater than 5 and less than 1/5, respectively. A weighted average of the two images provides better image quality than either individually. Volumetric reconstruction of the multi-channel P4-1 data visualizes anatomic features that are rarely seen in ultrasound, CT, or MRI.

CONCLUSION

VHF-induced thermoacoustic pulses can be detected by clinical ultrasound arrays. Quantitative imaging can be achieved using transducers and electronics with sensitivity to kHz frequencies.

CLINICAL RELEVANCE/APPLICATION

VHF-induced thermoacoustics requires propagating powerful EM pulses, similar to B1 excitation pulses used in MRI, but without the need for a costly superconducting magnet.

SSA20-05 Intra-Operative Cerebral Angio-Sonography with Ultrasound Contrast Agents

Background

Intra-operative vessels visualization is highly desirable in neurosurgery, especially when the target is related or close to main vessels, such as in skull base and vascular surgery. Contrast enhanced ultrasound (CEUS) is an imaging technique that allows visualization of tissue perfusion and vascularization, through the infusion of purely intravascular ultrasound contrast agents (UCA).

Evaluation

After cerebral scanning with B-mode ultrasound (US) CEUS is performed: UCA are injected and insonated with low mechanical index US. UCA specific harmonic signal is transduced using contrast specific algorithm, to obtain real-time angio-sonography (ASG).

Discussion

ASG depicts flow entity and direction in the target vessels, through the visual qualitative detection of movement, velocity and number of MB. Through the UCA dynamics it is possible to study all the vascular districts simultaneously, both arterial and venous, without the necessity to set gain or pulse repetition frequency as in Doppler imaging that however permits to quantify the flow; 3 phases of enhancement are notable: arterial, parenchymal and venous. ASG, being an echotomographic examination, provides a representation of the vessels within the surgical fields, not only on the surface, as showed by microscopic fluorescence, but also of those deeply seated and still embedded within the surgical field, allowing to visualize them in depth and follow their entire course simply tilting the probe.

Conclusion

Real time intra-operative ASG is a rapid, reliable, repeatable method for vessels visualization and evaluation of tissue perfusion.

SSA20-06 A New AEC Set-up Achieves Constant Lesion Detectability for Different Breast Thicknesses in Digital Mammography

Purpose

Bandwidth for quantitative whole organ imaging. This is an important step because thermoacoustic signal strength is directly proportional to SAR, which is lower in the VHF regime than in microwave or optical regimes.

METHOD AND MATERIALS

A 96-channel transducer array (P4-1) providing 3 cm coverage was incorporated into a benchtop thermoacoustic imaging system for imaging fresh surgical specimens. Thermoacoustic signal was generated by 700 ns irradiation pulses with 11 kV/m electric field strength. Data was acquired simultaneously in step-and-shoot mode by the array and a 2.25 MHz focused single-element transducer. In-plane resolution and contrast were measured by imaging an 80-micron wire and a homogeneous cylindrical phantom. Several fresh human prostates were imaged immediately after surgery. Two sets of sinograms were acquired, separated by a 2 cm translation along the tomographic axis. The P4-1 data was reconstructed over a 6 x 6 x 5 cm³ volume. Rudimentary comparison to histology was performed.
To investigate detectability of simulated lesions in real mammograms for different breast thicknesses and 2 set-ups for automatic exposure control (AEC).

**METHOD AND MATERIALS**

520 screening mammograms, acquired under standard AEC mode, were selected and divided into 4 thickness groups (T-groups), T1=29mm, T2=30-49mm, T3=50-69mm, T4=70mm. Each group contained 130 cranio-caudal lesion-free images. BIRADS density scores and Volpara density maps were available for each image. Simulated lesions of microcalcification clusters and masses were inserted into half of the images. A specific lesion template was inserted into one image of each T-group having the same BIRADS score and local Volpara value in order to separate the influence of thickness from the background. A new AEC set-up, designed to give constant theoretical object detectability as a function of thickness rather than constant detector pixel value. Modified AEC was then implemented for breast thicknesses above 30 mm resulting in an average dose increase of 60%. New patient data were collected and lesion insertion was repeated for the new dataset. Four radiologists performed a free search study on both datasets. JAFROC analysis was then applied. The alternative free-response receiver operating characteristic (AFROC) areas were calculated for each T-group.

**RESULTS**

For standard AEC mode: AFROC area decreases from 0.802 to 0.553 with increasing thickness for groups T1 to T3 while the area for T4 (0.565) was found almost equal to T3 (0.553). All p-values were smaller than 0.05 except for the T3-T4 pair. Detection differences between T3 and T4 were not significantly different, while the decreasing trend from T1 to T3 is significant. For the modified AEC mode: the AFROC area for T1 was equal to 0.802, while for T2, T3 and T4 it was equal to respectively 0.650, 0.652 and 0.652. No significant differences were found for these T-groups (p-values>0.05) while T1 remained significantly different from all others T-groups.

**CONCLUSION**

A significant decrease in lesion detection for increasing breast thickness is seen when the standard AEC mode is used. The modified AEC mode instead provided constant lesion detection for breast thicknesses above 30mm.

**CLINICAL RELEVANCE/APPLICATION**

This study quantifies the influence of breast thickness on lesion detectability and proposes a new AEC set-up with improved detectability for digital mammographic systems.

**SSA20-07 X-ray Attenuation of Normal and Cancerous Breast Tissue Measured with Photon-counting Spectral Imaging**

Sunday, Nov. 29 11:45AM - 11:55AM Location: S404AB

Matthew G. Wallis, MD, Cambridge, United Kingdom (Abstract Co-Author) Nothing to Disclose
Elin Moa, MS, Solna, Sweden (Abstract Co-Author) Employee, Koninklijke Philips NV

**PURPOSE**

Spectral imaging is emerging as a promising method to extract quantitative information from x-ray images, applied in mammography to improve lesion visibility, discriminate between lesion types, and measure breast density. Common for the development of these applications is that prior knowledge of tissue x-ray attenuation is required, but the sources of such information are sparse. Moreover, attenuation is often measured on formalin-fixed tissue specimens, but the effect of such fixation on the obtained attenuation values is largely unknown. The purpose of this study is to measure the attenuation of fresh and fixed samples of normal and cancerous breast tissue.

**METHOD AND MATERIALS**

7 samples of adipose breast tissue, 3 samples of glandular tissue and 8 samples of tumor tissue in the thickness range 3-12mm were imaged on a photon-counting spectral mammography system before and after formalin fixation. The energy dependent x-ray attenuation was measured in terms of equivalent thicknesses of aluminum (Al) and poly-methyl methacrylate (PMMA) for 10mm of tissue.

**RESULTS**

Figure 1 shows the equivalent Al and PMMA thicknesses (mean +1 standard deviation of individual samples): -0.110±0.022mm Al, 8.60±0.13mm PMMA for fresh adipose tissue, 0.268±0.040mm Al, 8.44±0.26mm PMMA for glandular tissue, 0.312±0.024mm Al, 8.55±0.17mm PMMA for tumor tissue. The difference between fixed and fresh tissue were -0.007mm Al, 0.01mm PMMA for adipose tissue, -0.041mm Al, 0.22mm PMMA for glandular tissue, and -0.039mm Al, 0.07mm PMMA for tumor tissue.

**CONCLUSION**

There was a measurable difference in attenuation between fresh and fixed tissue that was consistent for all investigated tissue types. There was a relatively large difference between glandular and tumor tissue, but the number of samples is still too limited to show significance. The equivalent PMMA thicknesses were slightly higher than values derived from published data (Hammerstein 1979, Johns and Yaffe 1987), but the Al thicknesses agreed well values derived from Johns and Yaffe.

**CLINICAL RELEVANCE/APPLICATION**

Accurate data on tissue attenuation is crucial for the development and implementation of spectral imaging techniques, which can potentially improve sensitivity and specificity of mammography.

**SSA20-08 Dedicated High-Resolution Breast CT Allows Imaging Micro-Calcifications down to 130 µm at Screening Mammography Dose Levels**

**PURPOSE**

Dedicated high-resolution breast CT is emerging as a promising method to extract quantitative information from x-ray images, applied in mammography to improve lesion visibility, discriminate between lesion types, and measure breast density. Common for the development of these applications is that prior knowledge of tissue x-ray attenuation is required, but the sources of such information are sparse. Moreover, attenuation is often measured on formalin-fixed tissue specimens, but the effect of such fixation on the obtained attenuation values is largely unknown. The purpose of this study is to measure the attenuation of fresh and fixed samples of normal and cancerous breast tissue.
Computed tomography of the breast (BCT) has been a topic of interest for about two decades. It was proposed and evaluated in different designs by a number of groups as a potential alternative method for breast imaging. So far efforts have shown success with respect to soft tissue imaging but suffer from limited spatial resolution. We designed and evaluated a BCT scanner aiming for three-dimensional (3D) spatial resolution of better than 100 µm to provide means for improved assessment of 3D micro-calcification clusters.

**METHOD AND MATERIALS**

The concept of the scanner is built on fast spiral CT using directly converting cadmium telluride detector technology with 100 µm pixel pitch; it was evaluated and confirmed previously by simulations. Here we assessed spatial resolution on a prototype setup by measuring the modulation transfer function (MTF) using a 10 µm diameter tungsten wire. High precision Ruby beads immersed in a plastic breast-mimicking setup and 10 surgically resected breast specimens were measured in direct comparison to full field digital mammography (FFDM). The same 60 kV scan protocol was used for all BCT measurements; standard clinical settings were used for FFDM imaging. Micro-CT at 30 µm resolution was employed as reference standard for judging the specimen results.

**RESULTS**

BCT exposures were kept at a level corresponding to below 6 mGy average glandular dose related to exposure of a tissue-equivalent cylinder of 14 cm diameter. Spatial resolution characterized by the MTF's 10% value was measured as 64 lp/cm. Ruby beads were clearly visible in BCT exams down to 130 µm, the smallest size available; FFDM revealed beads down to 160 µm. Specimen examinations confirmed these results qualitatively. For specimens, BCT showed micro-calcifications down to 100 µm; it was vastly superior in separating structures in different layers by virtue of its slice imaging nature.

**CONCLUSION**

High-resolution BCT allows improving the assessment of 3D micro-calcification clusters and avoids erroneous superimposition effects, which may pretend fictitious lesions in projection imaging.

**CLINICAL RELEVANCE/APPLICATION**

Breast CT offering high resolution in all three dimensions shall enable improved analysis and diagnostics of micro-calcifications.
The microcalcification detection performance in multi-contrast breast imaging is strongly influenced by both anatomical noise and radiation dose level. The results presented here offer new insight into how each individual modality can be optimized to maximize the likelihood of detecting early breast cancers.

CLINICAL RELEVANCE/APPLICATION

Understanding how additional information from DPC and DF imaging may aid in breast cancer is a crucial step in designing next generation multi-contrast breast imaging systems.
PURPOSE
To determine the association of COPD and COPD phenotypes (emphysema, airway and mixed) with lung cancer (LC) in participants with indeterminate lung nodules in the National Lung Screening Trial (NLST).

METHOD AND MATERIALS
We conducted a retrospective, case-control study of 817 participants (200 LC, 617 controls) in the CT-trial arm with 6-19 mm indeterminate lung nodules. 8 readers performed a visual analysis for centrilobular emphysema (CLE), bronchial wall thickening, centrilobular nodularity and interstitial fibrosis. Readers were asked to classify each scan as normal, emphysema-predominant COPD, airway-predominant COPD or mixed pattern COPD. Spirometry results (FEV1/FVC, FEV1) were used to classify each participant as normal or mild, moderate, severe or very severe COPD.

RESULTS
In a univariate analysis for LC diagnosis, emphysema-predominant COPD phenotype had an odds ratio (OR) of 1.530 (95% confidence interval (CI): 0.994, 2.354), airway-predominant COPD an OR of 1.004 (95% CI: 0.619, 1.629) and the mixed pattern an OR of 0.764 (95% CI: 0.427, 1.367) (reference = normal). Increasing CLE severity was associated with LC diagnosis for trace (OR 1.378, 95% CI: 0.879, 2.160), mild (OR 1.704, 95% CI: 1.073, 2.706) and moderate (OR 2.133, 95% CI: 1.326, 3.431). The number of patients with severe CLE was small with inconclusive results (OR 1.105, 95% CI: 0.580, 2.103). Increasing airflow limitation was not strongly associated with increasing odds ratios for LC [mild OR 0.917 (95% CI: 0.533, 1.577), moderate OR 1.278 (95% CI: 0.865, 1.889), severe OR 0.939 (95% CI: 0.525, 1.681), very severe OR 2.040 (95% CI: 0.653, 6.374), reference normal].

CONCLUSION
Both an emphysema-predominant COPD phenotype by CT and increasing severity of CLE were associated with an increased LC risk in patients with indeterminate lung nodules on CT screening, while airflow limitation had a less strong relationship. The latter may be due to the lack of specificity of COPD phenotype available from spirometry. The NLST received funding from the National Cancer Institute through the grants U01 CA079778 and U01CA 080098.

CLINICAL RELEVANCE/APPLICATION
Risk calculation for indeterminate nodules incorporates COPD history. CT information on both emphysema-predominant COPD phenotype and severity may perform better in risk prediction than spirometry.

Lung Nodule Consistency and Relative Risk of Future Lung Cancer Diagnosis: Does Sex Matter?

Participants

Philip M. Boiselle, MD, Boston, MA (Presenter) Nothing to Disclose
Fenghai Duan, PhD, Providence, RI (Abstract Co-Author) Nothing to Disclose
Stavroula Chysanthopoulou, Providence, RI (Abstract Co-Author) Nothing to Disclose
Sarah DeMello, Providence, RI (Abstract Co-Author) Nothing to Disclose
Denise R. Aberle, MD, Los Angeles, CA (Abstract Co-Author) Nothing to Disclose
Caroline Chiles, MD, Winston-Salem, NC (Abstract Co-Author) Nothing to Disclose

PURPOSE

To compare differences in the relative risk (RR) of lung cancer (LC) by nodule consistency and sex in the CT arm of the NLST.

METHOD AND MATERIALS

By study design, all CT-detected nodules measuring 4–30 mm were characterized by consistency (solid=SN, nonsolid/ground glass=GGN, and part-solid=PSN). For each nodule consistency, the following were calculated: sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for LC for both men (M) and women (W). For each nodule consistency, RR was calculated as the ratio of the probability of LC given a reported nodule consistency to the probability of LC given no nodule of the same consistency.

RESULTS

Of 26,455 participants in the CT arm of the NLST, 9994 (37.8%) had a positive screen at ≥ 1 time point. 8062 (81%) had 1 nodule consistency and 1932 (19%) had >1 nodule consistency. The RR of LC was significantly higher for women than men for GGNs (2.68 W vs.1.68 M, p=0.0026), and a similar trend was observed for PSNs (4.45 W vs. 3.19 M, p=0.0556). In contrast, SNs were associated with a comparable RR for both sexes (4.48 vs. 3.77, p=0.1970), along with nearly equivalent sensitivity and specificity for LC (sensitivity = 69.6% W, 68.5%M; specificity = 69.6% W, 68.5% M). Women demonstrated a higher sensitivity than men for subsolid nodules, including GGNs (26.7% W, 12.6% M) and PSNs (16.2% W, 10.2% M). PSNs had the highest PPV in both sexes (15.3% W, 12.3%, M), whereas SNs had the lowest PPV in women (7.9%) and GGNs had the lowest PPV in men (6.6%).

CONCLUSION

Rates of lung cancer are influenced by both nodule consistency and sex. Subsolid nodules are associated with a higher risk of lung cancer for women than men.

CLINICAL RELEVANCE/APPLICATION

Radiologists should be aware of sex-related differences in risk of lung cancer for subsolid nodules when interpreting CT screening studies.

Phillip M. Boiselle, MD - 2012 Honored Educator
expert radiologist. Completely calcified nodules and perifissural nodules were given a score of 0, in accordance with the McWilliams model. All nodules were categorized into their Lung-RADS category based on nodule type and diameter. Perifissural nodules were treated as regular solid nodules, in accordance with Lung-RADS guidelines. Sensitivity and specificity were calculated, for each Lung-RADS category cut-off. For each specificity level, corresponding sensitivity of the McWilliams model was determined.

RESULTS

McWilliams performed substantially better than Lung-RADS in selecting malignant nodules for more aggressive follow-up. Defining Lung-RADS category 2/3/4A/4B and up as a positive screening result, nodule malignancy specificity was 21%/65%/86%/99% and sensitivity was 100%/85%/58%/32%. At the same specificities, McWilliams's sensitivity was higher with 100%/96%/86%/45%.

CONCLUSION

For every cut-off level in Lung-RADS, the McWilliams model operating at the same specificity has superior sensitivity to differentiate malignant from benign nodules.

CLINICAL RELEVANCE/APPLICATION

The McWilliams model seems to be a better tool than Lung-RADS to provide a malignancy risk and help radiologists determine which subgroup of nodules detected in a screening setting need more invasive work-up.

SSA04-05  Sex- and Gender-linked Differences in Baseline Characteristics of the National Lung Screening Trial

Participants

Caroline Chiles, MD, Winston-Salem, NC (Presenter) Nothing to Disclose
Fenghai Duan, PhD, Providence, RI (Abstract Co-Author) Nothing to Disclose
Judith K. Amorosa, MD, Somerville, NJ (Abstract Co-Author) Nothing to Disclose

Martin Tammemagi, PhD, St Catherines, ON (Abstract Co-Author) Nothing to Disclose
Phillip M. Boiselle, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose

PURPOSE

Evaluate baseline characteristics of male and female participants in the National Lung Screening Trial (NLST) to determine sex- and gender-linked differences at enrollment that could influence trial results in terms of lung cancer (LC) risk.

METHOD AND MATERIALS

The NLST enrolled men (M) and women (W) aged 55 - 74, current or former smokers with > 30 pack-year smoking history. At registration, all participants completed questionnaires regarding demographics, personal/family history of cancer, and smoking history. Demographic characteristics of these participants were stratified by sex and compared with LC risk as determined by the Prostate Lung Colon Ovarian (PLCO) screening trial logistic-regression model for lung cancer prediction (PLCOM2012). Using this model, the mean 6-yr risk of LC was calculated for M and W participants.

RESULTS

Baseline characteristics that increase LC risk in female NLST participants included their lower educational level [13.62 years ± 2.28 (W), 14.05 years ± 2.49 (M)], lower BMI [28 (W), 29 (M)], higher self-reported history of COPD [6.44% (W), 4.08% (M)], and higher family history of LC [23.78% (W), 20.32% (M)], p<0.001 for all comparisons. Baseline characteristics that decrease their LC risk included younger age [61.2 (W), 61.6 years (M)], decreased smoking intensity [26.64 cigarettes per day (W), 29.69 (M), p<0.001], and shorter smoking duration [39.24 yrs (W), 40.27 (M), p<0.001 for all comparisons. Based on the PLCOM2012 model for lung cancer prediction, the mean calculated 6-yr LC risks were similar for both sexes [0.0319 ± 0.0274 (W), 0.0323 ± 0.0283 (M), p=0.07].

CONCLUSION

Despite significant differences in a variety of individual LC predictors between men and women, the mean calculated 6-yr risk of LC was similar for male and female NLST participants. These findings are consistent with reported similar lung cancer incidence rates between men and women within each trial arm of the NLST.

CLINICAL RELEVANCE/APPLICATION

Risk factors for LC may vary according to sex characteristics. Including these in risk modeling may improve selection of individual patients for screening.

Claudia I. Henschke, MD, PhD, New York, NY (Abstract Co-Author) Nothing to Disclose

PURPOSE
Lung cancer screening with computed tomography (CT) reduces mortality in high-risk patients with a smoking history. The rate of lung cancers detected based on positive screening CT in the National Lung Screening Trial (NLST) was 2.4%. The aim of this study was to assess the radiological findings in a cohort of patients with a previous history of malignancy, who underwent CT screening for lung cancer.

METHOD AND MATERIALS
The IRB approved this study. Patients with a previous history of a malignancy, either cured from that disease or with a life expectancy of at least 5 years, were referred for low dose CT lung cancer screening between 5/2/2011 and 9/24/2014. Initial CTs and all available follow up CTs were retrospectively reviewed by 2 radiologists in consensus. CT features assessed included nodule size, morphology and number. Clinical features recorded included pack year smoking history, type of previous cancer and previous cancer therapy. The Lung-RADS™ scoring system was retrospectively applied to all studies.

RESULTS
140 patients were studied. 61 (43%) male, 79 (56%) female, mean age 66 (40-80). 139 patients (99%) had a smoking history [mean pack years 57 (0-120)]. All had a previous history of cancer: 58 (41%) breast, 21 (15%) head and neck and 17(12%) lung. All patients had at least 1 chest CT, 42 had 2 CTs, 30 had 3 CTs and 9 had at least 4 CTs. 8 (6%) patients were diagnosed with cancer on screening CT (7 lung carcinoma, 1 chest wall sarcoma). 2 (1%) patients had a biopsy or surgery for lesions identified on screening CT (1 atypical pneumocyte hyperplasia, 1 nodular scar). 49 (35%) patients were considered to have a positive screening CT (recalled for repeat chest CT earlier than 330 days), 33 (23%) after the 1st screen, 16 (20%) after the 2nd screen, and 6 (15%) after the 3rd screen. After the 1st screen, the Lung-RADS™ categories were: 4 - 6%, 3 - 9% and < 2- 84%. The most common incidental findings were emphysema 26%, post-surgical change 8% and post-radiation change 16%.

CONCLUSION
Patients with a previous history of a malignancy undergoing screening chest CT have a higher rate of screen detected neoplasm as compared to the incidence reported in a non oncologic group such as the NLST.

CLINICAL RELEVANCE/APPLICATION
Patients with a prior cancer history have a higher rate of screen detected lung cancer than reported in the NLST. Larger studies are needed in this group who may benefit from lung cancer screening.
New solid nodules are common findings in CT lung cancer screening and carry a substantial risk of malignancy. More research concerning new nodules is necessary to determine a sufficient follow-up strategy and evaluate distinguishing nodule features of malignancy.

CONCLUSION
Lung cancer diagnosis during baseline screening was made in the largest nodule in 60/62 (96.8%) participants (cancer rate 4.0%). Mean nodule count in subjects with only benign nodules was 2.1±1.8, compared to 2.3±2.2 (p=NS) in screennees with lung cancer. The probability of lung cancer was 61/1746 (3.5%) in case a participant had one nodule, 37/800 (4.6%) for two nodules, 17/354 (4.8%) for three nodules, 12/191 (6.3%) for four nodules and 10/301 (3.3%) when a participant had over four nodules (p=NS). Lung cancer diagnosis during baseline screening was made in the largest nodule in 60/62 (96.8%) cases.

CONCLUSION
Multi-nodularity is common in baseline CT lung cancer screening. The relationship between nodule count and lung cancer probability is complex, with a possible peak in probability of malignancy in subjects with four nodules. Lung cancer was detected most frequently in the nodule with the largest volume.

CLINICAL RELEVANCE/APPLICATION
Malignancy probability does not change with the increase of the number of lung nodules in a patient. Each nodule found in lung cancer screening subjects should be assessed separately, with recommendation for nodule management based on the nodule with the largest volume.

SSA04-08 Occurrence and Lung Cancer Probability of Newly Detected Solid Nodules at Incidence CT Lung Cancer Screening

Participants
Robin Peters, MD, Groningen, Netherlands (Abstract Co-Author) Nothing to Disclose
Marjolein A. Heuvelmans, BSc, Groningen, Netherlands (Presenter) Nothing to Disclose
Peter M. Van Ooijen, Groningen, Netherlands (Abstract Co-Author) Nothing to Disclose

Matthijs Oudkerk, MD, PhD, Groningen, Netherlands (Abstract Co-Author) Nothing to Disclose

PURPOSE
To investigate the association of pulmonary multi-nodularity with lung cancer probability in baseline computed tomography (CT) lung cancer screening.

METHOD AND MATERIALS
In a low-dose CT lung cancer screening trial, participants were selected with at least one non-calcified nodule at baseline. The trial was approved by the Ministry of Health. All participants gave informed consent. The per-participant number of baseline nodules was determined. The probability of lung cancer was compared for categories based on number of baseline nodules using chi-square testing. Lung cancer diagnosis was confirmed by histology. Nodules were classified as benign if they did not show significant growth for up to six years after baseline.

RESULTS
3,392 participants with 7,258 nodules were included. 1,746/3392 participants (51.5%) had one nodule, 800/3392 (23.6%) had two nodules, 354/3392 (10.4%) had three nodules, 191/3392 (5.6%) had four nodules, and 301/3392 (8.9%) had over four nodules at baseline. Lung cancer was diagnosed in these nodules during baseline in 62 participants, and during later rounds in another 75 participants (cancer rate 4.0%). Mean nodule count in subjects with only benign nodules was 2.1±1.8, compared to 2.3±2.2 (p=NS) in screennees with lung cancer. The probability of lung cancer was 61/1746 (3.5%) in case a participant had one nodule, 37/800 (4.6%) for two nodules, 17/354 (4.8%) for three nodules, 12/191 (6.3%) for four nodules and 10/301 (3.3%) when a participant had over four nodules (p=NS). Lung cancer diagnosis during baseline screening was made in the largest nodule in 60/62 (96.8%) cases.

CONCLUSION
Multi-nodularity is common in baseline CT lung cancer screening. The relationship between nodule count and lung cancer probability is complex, with a possible peak in probability of malignancy in subjects with four nodules. Lung cancer was detected most frequently in the nodule with the largest volume.
benign and malignant new nodules.

**CLINICAL RELEVANCE/APPLICATION**

During LDCT lung cancer screening, in almost 8% of participants with new solid nodules, one of these nodules is malignant and guidelines may need to consider a more stringent follow-up for new nodules.

**SSA04-09 Comparing Inter-reader Variability of Manual Diameter and Semi-automated Volumetric Measurements for Pulmonary Nodules in Lung Cancer Screening**

Sunday, Nov. 29 12:05PM - 12:15PM Location: S404CD

Participants

Arjun Nair, MD, FRCR, London, United Kingdom (Presenter) Nothing to Disclose

Sze Mun Mak, MBBS, FRCR, London, United Kingdom (Abstract Co-Author) Nothing to Disclose

Nicholas J. Screaton, BMBCh, Cambridge, United Kingdom (Abstract Co-Author) Nothing to Disclose

David R. Baldwin, MD, Nottingham, United Kingdom (Abstract Co-Author) Nothing to Disclose

Anand Devaraj, MBBS, London, United Kingdom (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

Guidelines propose that solid nodules with baseline diameter<6mm return to annual lung cancer screening. However, the accepted range of inter-reader variability (IRV) in manual diameter measurements derives from a single study. We aimed to (1) quantify IRV for both manual diameter and semi-automated volumetric measurements (Vol), and (2) assess inter-reader agreement for diameter-based categorisation, for solid nodules that may potentially require CT follow-up based on their volumes.

**METHOD AND MATERIALS**

Solid nodules between 50-300mm³ that had been measured by two trial radiologists at baseline CT in a national lung screening trial were reviewed. Two radiologists also independently measured diameters using electronic callipers. Diameter measurements were used to categorise nodules according to Lung-RADS for each reader. IRV was calculated using Bland-Altman analysis for diameter and volume measurements in all nodules, and for nodules ≥6mm. Inter-reader agreement for Lung-RADS categorisation was compared using the weighted kappa statistic (multirater K). The percentage of nodules where readers would have disagreed on the need for CT follow-up, using diameters according to Lung-RADS, was calculated.

**RESULTS**

286 nodules (mean diameter 5.0 ± 1.2mm, mean volume 99.5 ± 51.8mm³) in 200 subjects were studied. Absolute and percentage mean (and 95% confidence intervals, CIs) difference between readers were 0.2 (-1.2,1.6) mm and 4.5% (-22.7%, 31.6%) respectively for diameter, and 4.6(-101.6, 110.8) mm³ and 1.3% (-19.9%, 22.6%) respectively for volume. Percentage mean (and 95% CIs) differences between readers for diameter and volume in the 54/286 nodules measuring ≥6mm were 3.0% (-27.2%, 33.3%) and 0.1% (-1.1%, 1.4%). Multirater K for Lung-RADS categorisation was 0.67. Radiologists would have disagreed on the need for CT follow-up using diameter in Lung-RADS in 18/286 nodules (10.9%).

**CONCLUSION**

IRV in diameter is slightly higher than in semi-automated volumetry, for solid nodules with volumes 50-300mm³, but substantially lower using volumetry for nodules measuring ≥6mm in this volume range. However, inter-reader agreement for categorisation according to diameter remains good.

**CLINICAL RELEVANCE/APPLICATION**

Diameter measurement provides good overall agreement for nodule categorisation, but size reproducibility could substantially be improved using semi-automated volumetry for nodules deemed positive.

Shunsuke Terasaka, MD,PhD, Sapporo, Japan (Abstract Co-Author) Nothing to Disclose
Hiroki Shirato, MD, PhD, Sapporo, Japan (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

Direct electrical conductivity measurements to identify tumor location, before the era of CT and MRI, had documented difference in electrical conductivity values of tumors from normal brain parenchyma and among tumor types. Recent advances in MRI have allowed noninvasive measurement of electrical conductivity values. This study aimed to noninvasively determine the electrical conductivity characteristics of glioma and evaluate potential usefulness of noninvasive electrical conductivity measurement in glioma evaluation.

**RESULTS**

The contrast-enhanced tumor component of grade III gliomas had higher mean and mode of electrical conductivity histograms than the non-contrast-enhanced tumor component and normal-appearing brain parenchyma (P<0.017). The non-contrast-enhanced tumor component of grade II gliomas had higher mean electrical conductivity than the normal brain parenchyma (P=0.012). Mode of electrical conductivity histograms for both components of grade IV tumors were higher than grade III tumors (P<0.017).

**CONCLUSION**

The electrical conductivity characteristics of glioma were determined noninvasively by MRI. Electrical conductivity difference of gliomas from the normal brain parenchyma and between tumor grades suggests potential usefulness of noninvasive electrical conductivity measurements.

**CLINICAL RELEVANCE/APPLICATION**

Information about tissue electrical conductivity can be obtained noninvasively by MRI; and this information can be beneficial in distinguishing gliomas.

**SSA18-02 Symptomatic Seizures in Primary Glioblastoma: A Radiogenomic Approach towards a Possible Prognostic Factor**

Sunday, Nov. 29 10:55AM - 11:05AM Location: N229

**Participants**
Vera C. Keil, MD, Bonn, Germany (Presenter) Nothing to Disclose
Tunc F. Ersoy, Bonn, Germany (Abstract Co-Author) Nothing to Disclose
Dariusch R. Hadizadeh Kharrazi, MD, Bonn, Germany (Abstract Co-Author) Nothing to Disclose
Hans H. Schild, MD, Bonn, Germany (Abstract Co-Author) Nothing to Disclose
Matthias Simon, Bonn, Germany (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

In patients with primary glioblastoma (pGB), tumor-induced seizures (TIS) are a common symptom and are possibly a positive prognostic factor for progression free and overall survival (PFS, OS). Explanations of the pathogenesis of TIS range from tumor location and pressure effects to neurochemical particularities based on the genetic profile of the tumor. This study evaluates if TIS in pGB can be correlated with imaging or genetic aspects of the lesion.

**METHOD AND MATERIALS**

Retrospective analysis of pre-operative 3 T MRI brain scans (Achieva TX; Philips Healthcare) of 64 pGB patients (29 with TIS; 35 without seizures). Analysis criteria: gender, age, PFS and OS, genetic profile (TERT mutation/rs2853669 polymorphism, MGMT promoter status), midline shift, subventricular pGB growth, bilitalery, multifocality as well as multiple volume ratios. Volumetry of contrast-enhancing (vital) tumor (CER), central necrosis (CN) and peri-focal FLAIR hyperintensities was based on 3D contrast-enhanced Tiw, T2w and FLAIRw maps. MRI were analyzed with post-processing software (Philips Intellispace) by three readers
independently. Statistic analyses were performed with SPSS 22.0 with TIS as the independent variable.

RESULTS
OS was significantly longer in pGB patients with TIS (p=0.004). There was a tendency for longer PFS in this group (p=0.08; mean 13.3 vs. 8.3 months). In pGB patients with TIS, total tumor volume was significantly smaller (p=0.017; 50.3 v. 29.4 cm³) and the tumor was significantly more often found in the subventricular zone, yet surprisingly not in the hippocampal area. TIS was not associated with any of the tested genetic markers known to be associated with longer OS and PS.

CONCLUSION
TIS in pGB patients could significantly be correlated with distinct imaging aspects of the tumor (size and location) as well as with longer OS and PFS. Commonly analyzed genetic markers for OS and PFS (MGMT, hTERT) were yet not associated with TIS.

CLINICAL RELEVANCE/APPLICATION
While TIS proved a prognostic factor for OS and PFS, this is not correlated with MGMT and hTERT status in pGB, but TIS does correlate with distinct imaging aspects on MRI. Whether TIS lead to earlier diagnoses of pGB and hence longer OS/PFS due to smaller tumor volume remains an intricate question to solve.

SSA18-03 Investigation into the Effect of Diagnostic Ultrasound and Microbubble on the Blood-Brain Tumor Barrier Permeability of C6 Glioma

Sunday, Nov. 29 11:05AM - 11:15AM Location: N229

Participants
Jinlong Zhang, PhD, Chongqing, China (Presenter) Nothing to Disclose
Weiguo Zhang, Chongqing, China (Abstract Co-Author) Nothing to Disclose

PURPOSE
To explore the effect of microbubble-enhanced diagnostic ultrasound (MEUS) on the blood-brain tumor barrier permeability and the possible mechanism.

METHOD AND MATERIALS
C6 Glioma-bearing Sprague-Dawley rats were assigned to 3 separate groups; the microbubble-enhanced continued diagnostic ultrasound group (CMEUS), the microbubble-enhanced intermittent diagnostic ultrasound group (IMEUS) and the control group. Rats were sonicated through skull with low-frequency diagnostic ultrasound and injected with Evans Blue (EB) dye and microbubbles through their tail veins to test changes in capillary permeability. Confocal laser scanning microscopy was used to observe the deposition of red fluorescence-dyed EB in tumor tissues. HE staining and MRI SWI were used to evaluate whether MEUS can damage normal brain tissue. The distribution and expressing levels of JAM-1 and calcium-activated potassium channels (Kca channels) was detected by western blot and immunohistochemical.

RESULTS
In the MEUS groups, EB exudation exhibited a significant increase in the tumor tissue compared with the control group. While the IMEUS group had more EB exudation than the CMEUS group. LSCM showed that a bright red fluorescence of EB was extensively distributed in the tumor interstitium. Western blot and immunohistochemical revealed MEUS significantly increased Kca channel protein expression and reduced JAM-1 expression in glioma tissue. And this changes were more obvious in the IMEUS group than the CMEUS group.

CONCLUSION
MEUS could effectively increase blood-brain tumor barrier permeability without causing damage to normal nerve tissue. The mechanism might be up-regulation of Kca channels expression in glioma tissue and affecting the formation of tight junction in blood-brain tumor barrier by reduction of JAM-1 expression. These findings might provide some new guidance to find a therapeutic option to site-specific open the BTB and deliver anti-cancer agents to glioma.

CLINICAL RELEVANCE/APPLICATION
These findings might provide some new guidance to find a therapeutic option to site-specific open the BTB and deliver anti-cancer agents to glioma.

SSA18-04 Improved Clinical DCE-MRI Pipeline for High Resolution, Whole Brain Imaging: Application to Brain Tumor Patients

PURPOSE
To develop novel DCE-MRI acquisition, reconstruction, and processing approaches that are targeted towards providing complete clinical assessment of brain tumors.

METHOD AND MATERIALS
A clinical prospective evaluation of a novel sparse sampling and constrained reconstruction scheme to enable whole brain DCE-MRI
A clinical prospective evaluation of a novel sparse sampling and constrained reconstruction scheme to enable whole brain DCE-MRI imaging (22x22x20 cm³ coverage at spatial resolution of 0.9x0.9x1.9 mm³) is demonstrated. Our approach uses multiple sparsity constraints in the spatial and temporal domain, which are spatial wavelet, spatial total variation and temporal finite difference, all with low weights, to mitigate potential bias from any one constraint. We compare with a current clinical scan (Rate 2 SENSE: 22x22x4.2 cm³ at spatial resolution of 0.9x1.3x7 mm³) on 15 brain tumor (BT) patients. PK parameters (Ktrans, vp) were derived, and image quality scores (4 point Likert scale) from two experienced neuroradiologists were used to evaluate the anatomic images and PK maps. We also propose two novel constraints that leverage knowledge from the PK model, to improve the above constraints, and obtain reduced dependency on free parameters; these are evaluated in a retrospective undersampling study of 10 BT patients.

RESULTS

We obtained higher image quality scores with our experimental scan compared to the clinical scan. The combined radiologists scores for each of the time-resolved, post-contrast, Ktrans images, respectively for the accelerated and clinical scans were 1.2 ± 0.6 v/s 2.2 ± 0.7 (p < 0.001). Fig1 demonstrates two examples of improved volume coverage in imaging a patient with a 6 cm glioblastoma multiforme tumor, and a patient with 14 metastatic lesions spread throughout the brain. In the retrospective study, the novel PK derived constraints achieved improved PK parameter map depiction at acceleration rates greater than 20; (not shown)

CONCLUSION

A novel high resolution whole brain DCE-MRI method using constrained reconstruction that is clinically feasible is demonstrated; which constituted a substantial 36 fold improvement in resolution and coverage compared to current clinical scans

CLINICAL RELEVANCE/APPLICATION

The combined use of modern sparse sampling, and constrained reconstruction techniques enables whole brain isotropic high resolution DCE-MRI which greatly improves the clinical value of DCE-MRI in characterizing brain tumors (eg. guaranteed imaging of large tumors, multiple small lesions, assessment of anti-angiogenic therapies for brain tumors).

SSA18-05 Two-dimensional Localized Correlated Spectroscopy (2D L-COSY) at 7T for Detection of 2-hydroxyglutarate in Gliomas with IDH Mutations

Sunday, Nov. 29 11:25AM - 11:35AM Location: N229

PURPOSE

Mutations in the isocitrate dehydrogenase (IDH) 1 and 2 genes in oligodendroglioma, astrocytoma and secondary glioblastoma are associated with better prognosis. Previous magnetic resonance spectroscopy (MRS) studies have suggested the oncometabolite 2-hydroxyglutarate (2HG) as a potential biomarker for these mutant gliomas. Two-dimensional localized correlated spectroscopy (2D L-COSY) has demonstrated unambiguous and reliable measurement of several brain metabolites, including 2HG. Spectroscopy at ultra-high fields affords proportionally higher signal quality and spectral separation resulting in improved sensitivity and specificity. In this study we demonstrate the utility of 2D L-COSY for detection of 2HG in human gliomas.

METHOD AND MATERIALS

Seven brain tumor patients with prior magnetic resonance imaging/spectroscopy (MRI/MRS) scans at 3T were studied using 2D L-COSY on a 7T whole-body scanner with a 32-channel transmit/receive head coil. Scan parameters were as follows: TE = 20 ms, TR = 2 s, 8 averages, 64 Ax11 increments of 0.4 ms, 2048 t2 points with F2 bandwidth = 4000 Hz and F1 bandwidth = 2500 Hz, scan time 17 min. Voxels were localized using T2-weighted fluid-attenuated inversion recovery (FLAIR) imaging and ranged from 11-15 mL. L-COSY data were reconstructed offline using a custom MATLAB-based post-processing algorithm and quantified through peak volume integration. IDH1/2 mutation status was subsequently determined with pathology.

RESULTS

2D L-COSY detected 2HG peaks in two of the seven patients. A third patient was prospectively declared inconclusive due to artifact ridging in the region where 2HG would be expected. Pathology results confirmed IDH1 mutation in these three patients and the absence of mutation in the remaining four. 2D L-COSY further demonstrated the unambiguous separation of other metabolites including choline-containing metabolites like phosphocholine (PC) and glycerophosphocholine (GPC) and separation of lactate (Lac) from background lipid signal.

CONCLUSION

This study using 2D L-COSY represents the unambiguous detection of 2HG in vivo at 7T, which could serve as an biomarker for malignant progression in brain tumors.

CLINICAL RELEVANCE/APPLICATION

Pre-surgical detection of 2HG could alter treatment strategies as both an early marker for malignant progression and as an endpoint for targeted therapy (AGIOS 121 drug) against IDH1 mutation.
Habitat on Treatment-naïve MRI Predict Clinical Survival in Glioblastoma Patients

Participants

PURPOSE
To show the ability of using the novel amide proton transfer-weighted (APTW, sensitive to mobile proteins, such as those in the cytoplasm), as well as conventional magnetization transfer (MT, sensitive to semi-solid macromolecules) MRI signals as imaging biomarkers to differentiate primary CNS lymphomas (PCNSLs) from high grade gliomas (HGGs), and evaluate the correlations between APTW and MT imaging signals and nuclear-cytoplasm (N/C) ratios.

METHOD AND MATERIALS
Eleven patients with lymphomas and 21 patients with HGGs were studied. MT spectra over an offset range of ±6 ppm (eight acquisitions at ± 3.5 ppm to increase the signal-to-noise ratio) and the conventional MT ratio (MTR) at 15.6 ppm (2 kHz) were acquired. The multiple APTW signals and MTR signal were obtained and compared between PCNSLs and HGGs. The diagnostic performance was assessed with the receiver-operating-characteristic (ROC) analysis. Image analysis software (Image-Pro Plus) was applied to calculating N/C ratios on HandE sections.

RESULTS
The PCNSLs usually showed more homogeneous APTW hyperintensity (spatially compared to the normal brain tissue) than the HGGs. The maximum APTW signal (APTWmax) and APTW signal inhomogeneity (APTWmax-min = APTWmax - APTWmin) within a lesion were significantly lower (P < 0.05 and 0.001, resp.), while the MTR signal was significantly higher (P < 0.01) in PCNSLs than in HGG lesions. APTWmax-min had the highest area under the ROC (0.963) and accuracy (94.1%) in differentiating PCNSLs from HGGs. There were significantly larger N/C ratios in PCNSLs (1.69 ± 0.72) than in HGGs (0.55 ± 0.21; P < 0.01), consistent with the APTW and MTR measurements. There was a strong, significantly negative correlation between APTWmax and N/C ratio (R = 0.576, P < 0.01), and there was a moderate positive correlation between MTR and N/C ratio (R = 0.326, P < 0.084).

CONCLUSION
The endogenous protein-based APTW signal would be a valuable MRI biomarker that can to provide an additional value to identify PCNSLs and HGGs presurgically.

Clinical Relevance/Application
The addition of APT imaging to the currently used MRI protocol (including the conventional and advanced MRI sequences) would enhance the differential diagnostic accuracy of MRI between PCNSLs and HGGs ultimately.

Habitat on Treatment-naïve MRI Predict Clinical Survival in Glioblastoma Patients

Participants
Pallavi Tiwari, PhD, Cleveland, OH (Presenter) Nothing to Disclose

PURPOSE
Glioblastoma Multiforme (GBM) is a highly aggressive and heterogeneous brain tumor. Currently all GBM patients are given "one-dose-fit-all" treatment. Identification of prognostic markers can allow for personalized therapy options for GBM. The underlying hypothesis of this study is that the heterogeneity in GBM (due to subtle variations in tumor enhancement, cellular density, fibrosis, necrosis that are not visually appreciable on volumetric analysis of MRI) is prognostic and can be captured using computerized texture descriptors extracted from within different tumor compartments (enhancing tumor, necrotic core, edema). These compartments together define tumor "habitat", and computerized texture features from within the habitat can be predictive of short-term (STS) (overall survival (OS) <6-months) from long-term survival (LTS) (OS>24-months).

METHOD AND MATERIALS
A total of 62 3 Tesla MRI studies (27 STS, 35 LTS) with Gd-T1C, FLAIR, and T2w protocols were obtained from the TCIA repository. Enhancing tumor, and necrotic regions on Gd-T1 and edematous region jointly on T2-w and FLAIR, were manually segmented by an expert using Slicer 3D. 135 2-D texture descriptors on a per-voxel basis (e.g. co-occurrence matrices, gray-level dependence matrices, Gabor), and volumetric measurements were extracted from each oftumor, necrosis, edema compartments on every MRI protocol. Feature selection was used to identify most discriminative features with a random forest classifier trained via 3-fold cross validation. Kaplan-Meier (KM) curves were used for survival analysis, with correction for multiple hypothesis testing to identify features that were significantly (p<0.05) correlated with survival.

RESULTS
Contributions from top 18 texture features within the tumor habitat, (from edema, necrotic core, enhanced tumor), when analyzed together, were most significantly associated with survival, across Gd-T1-C (p=0.003), FLAIR (p=0.006), and T2-w (p=0.02) as compared to individual features, and volumetric measurements from the tumor habitat.
CONCLUSION
Computerized texture features when jointly interrogated across compartments within the tumor habitat appear more prognostic of clinical survival in GBM than features from enhancing tumor and tumor volume alone.

CLINICAL RELEVANCE/APPLICATION
Identifying MRI differences in survival characteristics for patients with long term and short-term survival can allow for designing personalized therapeutic decisions for GBM.

SSA18-08 Using Pre-Operative Dynamic Contrast-Enhanced MRI to Evaluate Tissue Factor Expression: A Potential Role in Prediction of Glioma Malignancy

Sunday, Nov. 29 11:55AM - 12:05PM Location: N229

Participants
Tian Xie, Chongqing, China (Presenter) Nothing to Disclose

Wei Xue, Chongqing, China (Abstract Co-Author) Nothing to Disclose
Weiguo Zhang, Chongqing, China (Abstract Co-Author) Nothing to Disclose

PURPOSE
To correlate dynamic contrast-enhanced MRI (DCE-MRI) parameters with tissue factor (TF) expression for assessing glioma malignancy

METHOD AND MATERIALS
Thirty-two patients with histopathologically diagnosed supratentorial glioma received DCE-MRI. Extended Tofts linear model based parameters(Ktrans, Kep, Ve, Vp) were obtained, which were analyzed by hot-spot and whole tumor cross-sectional method, as well as histogram. Four serial paraffin sections were stained with TF, CD105, CD34 and α-SMA, respectively. Percentage area of TF was calculated at 200 × magnification. Microvascular parameters were calculated at 100 x magnification, including microvascular density (MVD), microvascular area (MVA), proliferating capillary index (PCI), and microvessel pericyte coverage index (MCI). The correlation was performed between TF and multiple microvascular indexes, DCE-MRI parameters.

RESULTS
TF was associated with glioma grade and significantly correlated with proliferating capillary index (PCI), microvascular pericyte coverage index (MP) (r=0.798, p<.001; r=0.835, p<.001) and also showed moderate correlation with microvascular area (MVA) and microvessels density (MVD). Volume transfer constant from plasma to tissue (Ktrans) hot-spot value best correlated with TF (r=0.886, p<.001), followed by 90th percentile Ktrans value (r=0.801, p<.001). Moreover, histogram analysis of Ktrans value demonstrated that weak TF expression was associated with less heterogeneous and positively skewed distribution.

CONCLUSION
Correlation of TF with microvascular indexes indicated that TF tightly linked with glioma malignancy. And Ktrans parameters provided reliable estimation of TF expression in glioma patients.

CLINICAL RELEVANCE/APPLICATION
DCE-MRI could pre-operatively evaluate tissue factor expression, thus it can be utilized for assessing glioma malignancy, particularly on neovascularization, like vascular endothelium proliferation and pericytes coverage.

SSA18-09 Chemical Shift Imaging (CSI) for Detection of 2-Hydroxyglutarate (2HG) in Human Gliomas at 3T

Sunday, Nov. 29 12:05PM - 12:15PM Location: N229

Participants
Gaurav Verma, PhD, Philadelphia, PA (Presenter) Nothing to Disclose
Harish Poptani, PhD, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose

Suyash Mohan, MD, Philadelphia, PA (Abstract Co-Author) Consultant, ACR Image Metrix; Investigator, Rad Dx

PURPOSE
The "oncometabolite" 2-hydroxyglutarate (2HG) has been shown to be an ideal biomarker for detection of isocitrate dehydrogenase (IDH) mutated gliomas. The presence of IDH mutation may be an early genetic marker of malignant transformation in gliomas and non-invasive detection of 2HG may aid in better treatment planning of these tumors. Chemical Shift Imaging (CSI) at 3T has been proposed for detection of 2HG and this study was performed to prospectively detect 2HG in tumors suspected of gliomas on imaging.

METHOD AND MATERIALS
Five patients were studied on a 3T scanner with a 12-channel receive head coil. Scan parameters were: TE=97 ms, TR=1.7s, NEX=3 with weighted phase-encoding, 1024 complex points, bandwidth=8000 Hz, 16x16 matrix, scan time 7 min. Voxels were localized using FLAIR or contrast enhanced images and were each 1 x 1 x 3 cm3. CSI data were reconstructed offline and quantified using the LCModel prior-knowledge based fitting program. A Cramer-Rao lower bound (CRLB) of 40% was used along with the criteria that multiple neighboring voxels show presence of 2HG. IDH1/2 mutation status was subsequently determined on pathology.

RESULTS
2HG resonance was detected in three patients who were later found to be: low grade (WHO Grade II, n=2) and high grade (WHO Grade III, n=1). The remaining two patients did not show a 2HG peak and were found to be: WHO grade IV, n=1; metastases, n=1. Presence of mutant IDH mutation was subsequently confirmed on pathology in all three patients where 2HG was detected while the
remaining two patients were IDH mutation negative.

**CONCLUSION**

LCModel fitting of CSI data successfully detected 2HG, confirming previous studies. This study further confirms the role of 2HG as a marker for malignant transformation indicating that IDH positive low grade gliomas where 2HG is detected should be treated more aggressively and can be ideal candidates for IDH targeted therapies.

**CLINICAL RELEVANCE/APPLICATION**

In vivo 2HG detection has significant translational implications: Early biomarker of malignant progression, treatment response and recurrence. Endpoint for therapy (AGIOS 121 drug) targeted against IDH1.
Multi-parametric quantitative MRI (qMRI) has long been an active field of research, with several approaches aiming to estimate a subset of $R_1$, $R_2$, $R_2^*$, proton density (PD) and magnetic susceptibility (QSM) maps of the tissues. We used a set of Steady-State sequences, acquired with variable flip angles (FAs) and different phase coherence, to derive, in a fully analytical way, quantitative volumetric $R_1$, $R_2$, $R_2^*$, PD and QSM maps.

Two dual-echo fully flow-compensated (FC) FLASH and one phase-cycled balanced Steady-State Free-Precession (bSSFP) sequences were acquired at different FAs with very low sensitivity to blood or Cerebrospinal Fluid (CSF) flow. The full brain of each volunteer was scanned in a total acquisition time of 14 minutes with a voxel size of 0.6 mm$^3$. The datasets were processed to remove banding artifacts and used to invert voxelwise the relaxometry equations in the FOV.

Unlike most existing approaches, the maps obtained by our method entirely rely on widely available 3D sequences, thus overcoming usual 2D resolution constraints, and are not affected by intra-voxel biases arising from imperfect 2D radio frequency-pulse profiles, which in turn cause different isochromat evolutions in response to different effective FAs. Moreover, unlike other 3D schemes based on unbalanced SSFP, our method does not suffer from high sensitivity to flow of relatively long $T_2$ fluids (as CSF), thus being apt to image other body districts. Also, several issues of the DESPOT methods are solved. In particular, the $B_1^\pm$ inhomogeneity dependence can be either removed by providing a measured $B_1$ field map, if an ad hoc protocol is available on the scanner, or largely compensated for by the proposed information theory approach. Furthermore, a judicious use of the Bloch equations for the acquired MR signals proved useful to skip the acquisition of the high-FA bSSFPs required by DESPOT2, thus limiting the acquisition time and avoiding at once SAR issues and CSF pulsation artifacts.

Our method allows for the quantitation of 5 independent parameters and gets rid of the sensitivity to $B_0$ inhomogeneity by means of a fully analytical solution, thus also speeding up the computation step.

To develop a T2 qMRI mapping algorithm for the DE-TSE pulse sequence that is accurate over the full T2 biological range. To create a T2 mapping program that combines the exact dual echo T2 formula and the methods of maximum likelihood (ML) estimation for estimating long $T_2$ values. The dual echo turbo spin echo (DE-TSE) pulse sequence is consistently being adopted for routine clinical use and for research protocols: it is fast, efficient, highly resilient to susceptibility artifacts, and diffusion insensitive. It also has qMRI applications for mapping T2 and the proton density (PD). The main limitation in terms of qMRI is that only two echoes are
available for T2 mapping, thus limiting the accuracy range of T2 estimation. The purpose of this work was to develop a T2 qMRI mapping algorithm for the DE-TSE pulse sequence that is accurate over the full T2 biological range, from soft tissues to pure cerebrospinal fluid (CSF). Specifically, to create a T2 mapping program that combines the exact dual echo T2 formula as well as the methods of maximum likelihood (ML) estimation for estimating long T2 values. ML estimators are optimal in the sense that the variance of the estimates reaches asymptotically the greatest lower bound of the variance.

**Evaluation**

HE-MLE algorithm was programed in Mathcad using the formulation of Bonny et al. (MRM 1996; 36(2):287-293.) and used to process the images of a phantom and the head images of a volunteer. The T2 values were compared to those obtained with a single slice multi spin echo (mSE) sequence. The phantom T2 obtained with both techniques are graphed in Fig. 1a: linear correlation analysis reveals strong linear relationship (R2=0.9988) with a slope of 0.975.

**Discussion**

DE-TSE is available from all major MRI manufacturers and efficiently produces excellent PD- and T2-weighted images with high anatomic coverage in less than four minutes.

**Conclusion**

The developed hybrid exact maximum likelihood T2 qMRI algorithm produces accurate measurements over the full T2 biological spectrum and could extend the usefulness of the DE-TSE pulse sequence in clinical and research applications.

**PURPOSE**

We are investigating a radiomics approach to treatment response assessment of multiple myeloma (MM) using MRI. This study assessed the value of our developed MRI biomarkers as prognostic factors in patients with MM after autologous bone marrow transplant (BMT).

**METHOD AND MATERIALS**

With IRB approval, 63 pairs of spine MRI scans performed pre- and post-BMT (3-6 months) and clinical tests (< ± 7 days of post-MRI) were collected retrospectively from 63 MM patients. A 3D dynamic intensity entropy transformation (DIET) method was developed to transform MR T1-weighted signal voxel by voxel to a quantitative entropy enhancement value (qEEV), from which two MR image biomarkers, the mean difference in qEEV between the pre- and post-BMT MR scans over the vertebrae (m-qEEV) and the percentage of vertebrae with an increased qEEV in the post-BMT scan (p-qEEV), were derived for each patient to estimate progression-free survival. The values of age, gender, and the clinical test outcomes including M-protein in serum and urine, ratio of free light chain (FLC), % plasma cell (PC), beta-2-microglobulin and immunoglobulin levels were also assessed. Univariate analysis was performed with the Kaplan-Meier method and log-rank test, and multivariate analysis was performed with the Cox proportional hazards regress model, with respect to the time to progression (TTP) censored at 3 years.

**RESULTS**

The univariate analysis showed that the patients with optimal cutoff points of m-qEEV < -0.1 and p-qEEV < 10% determined by the maximally selected rank statistics had significantly shorter TTP ( P = 0.047 and P < 0.001, respectively). The age (<60), gender and all individual clinical tests in their normal ranges did not significantly predict longer TTP, except normal FLC ( P = 0.040) and PC ( P = 0.022). The multivariate analysis showed that the best predictive factor for TTP was p-qEEV ( P < 0.018; hazard ratio (HR) 31.2). Other factors such as m-qEEV ( P =0.276; HR=5.6), FLC ( P = 0.510; HR = 1.4) and PC ( P < 0.217; HR = 1.2) did not provide significant predictive value for TTP.

**CONCLUSION**

The study demonstrated the feasibility of using the quantitative MRI biomarker (p-qEEV) as prognostic predictor for patients with MM after BMT.

**CLINICAL RELEVANCE/APPLICATION**

MR-based radiomic biomarker with prognostic significance may improve the accuracy for staging and assessing treatment response for MM, allowing clinicians to optimize therapy for individual patients.
**SSA21-04  Validation of a Quantitative Masking Index for Digital Mammography**

Sunday, Nov. 29 11:15AM - 11:25AM Location: S405AB

**Participants**

James G. Mainprize, PhD, Toronto, ON (Presenter) Institutional research agreement, General Electric Company

Olivier Alonzo-Proulx, Toronto, ON (Abstract Co-Author) Institutional research agreement, General Electric Company

Martin J. Yaffe, PhD, Toronto, ON (Abstract Co-Author) Research collaboration, General Electric Company Founder, Matakina International Ltd Shareholder, Matakina International Ltd Co-founder, Mammographic Physics Inc

**PURPOSE**

Mammography has reduced sensitivity for detecting cancer in dense breasts, for which superposition of shadows of normal structures can "mask" the presence of cancer either by a loss of contrast or by the distracting complexity of the surrounding parenchymal structures. We have developed a quantitative measure of masking by evaluating the signal-to-noise ratio (SNR) of a localized model observer.

**METHOD AND MATERIALS**

On a grid of sub-regions (ROIs), the parenchymal texture was quantified by extracting the inverse power-law exponent, β, from the noise power spectrum (NPS). The localized detection task SNR, d_L, for a simulated 5 mm diameter lesion was estimated using a non-prewhitening observer and measurements of the system MTF, and NPS from each ROI. The resulting map of d_L is analyzed to extract the masking potential of each mammogram. The d_L maps were validated with a 4 alternative forced choice (4AFC) of a simulated lesion (diameter 5 mm) inserted into ROIs randomly selected from a single mammogram, across 7 β categories (0.5 intervals from 1.5-5.0). A second reader study compared a radiologist’s perception and accuracy to the d_L maps generated for a set of 78 screening cases.

**RESULTS**

The 4AFC study was performed on 20 mammograms and over 5000 ROIs. Preliminary results on one reader showed that mean d_L was highly correlated with inverse threshold lesion thickness (r=0.897, p<1e-10). In the second study, a radiologist estimated the probability of malignancy, BIRADS density and assessed the difficulty level of each case. Initial results showed a 36% difference (p<1e-6) in mean d_L between non-dense and dense mammograms and a 28% difference (p<1e-3) in mean d_L between "easy" and 'hard' images.

**CONCLUSION**

A quantitative measure of masking by background parenchyma has been developed. Strong correlation is seen with both breast density and texture. Two preliminary reader studies confirm that local task SNR tracks with reader performance, in both simulated conditions and clinical evaluations of mammograms.

**CLINICAL RELEVANCE/APPLICATION**

A measure of masking by mammographic density can have a number of applications, e.g., to conform to recent changes to BIRADS density assessment, to categorize mammograms that require more careful assessment, or as a selection tool to identify those women who should be invited to be screened with alternative technologies.

**SSA21-05  Virtual Monochromatic CT Numbers from a Dual-Energy MDCT Acquisition: Comparison between Single-Source Projection-Based and Dual-Source Image-Based Platforms in a Phantom Environment**

Sunday, Nov. 29 11:25AM - 11:35AM Location: S405AB

Andrew R. Barina, MD, Durham, NC (Abstract Co-Author) Nothing to Disclose

Danielle Mann, MD, Cary, NC (Abstract Co-Author) Nothing to Disclose

Sandra Stinnett, MS, MPH, Durham, NC (Abstract Co-Author) Nothing to Disclose

Kingshuk Choudhury, PhD, Durham, NC (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To investigate in a phantom experiment whether there is any variability in virtual monochromatic CT numbers from a dual energy MDCT acquisition, across single- and dual-source hardware implementations.

**METHOD AND MATERIALS**

A polyethylene terephthalate torso phantom, filled with water, was employed to simulate the human abdominal environment. This contained a cylindrical polypropylene bottle, filled with 12 mg/mL of iopamidol 300, with serially suspended polyethylene terephthalate spheres (15 and 18 mm) filled with two iodine-to saline iodine dilutions (0.8 mgI/mL and 1.2 mgI/mL). Dual energy (80/140 kVp) and single energy (100 and 120 kVp) scans were performed using single-source (HD750 GSI, GE Healthcare) and dual-source (SOMATOM Definition Flash, Siemens Healthcare) MDCT systems. Virtual monochromatic images were reconstructed at energy levels ranging from 40 to 140 keV (at 10 keV increments), in either the projection- or the image-space domains.

**RESULTS**

There were significant differences between the single-source projection-based platform and the dual-source image-based platform in the measured attenuation values of the simulated lesions tested (P <0.001, for all comparisons). The magnitude of these differences was greatest at lower monochromatic energy levels and at lower iodine concentrations. The dual energy hardware platform, the virtual monochromatic energy level, and the lesion iodine concentration had a highly statistically significant effect on the difference in the measured attenuation values between the two platforms, indicating that the platforms respond differently to changes in these variables (P <0.001, for all comparisons).

**CONCLUSION**
A significant variability in CT numbers exists between single-source projection-based and dual-source image-based virtual monochromatic datasets, as a function of the selected energy level and the lesion iodine content.

**CLINICAL RELEVANCE/APPLICATION**

The variability in monochromatic CT numbers between the two clinically available dual energy platforms may impact clinical decisions that depend on subtle differences in measured attenuation values. For example, when minimally-vascularized abdominal neoplasms are repeatedly imaged with different dual energy platforms, differences in measured attenuation values between the imaging studies due to variability between scanners might be erroneously attributed to changes in tumor vascularity.

**SSA21-06 Accuracy Enhancement with Deep Convolutional Neural Networks for Classifying Regional Texture Patterns of Diffuse Lung Disease in HRCT**

**Participants**
Guk-Bae Kim, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
Yeha Lee, Seoul, Korea, Republic Of (Abstract Co-Author) CEO, VUNO Korea Inc
Hyun-Jun Kim, Seoul, Korea, Republic Of (Abstract Co-Author) Founder, VUNO Korea Inc

Joon Beom Seo, MD, PhD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose
June-Goo Lee, PhD, Seoul, Korea, Republic Of (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
To introduce deep learning-based feature extraction method which adaptively learns the most significant features for the given task using deep structure to classify six kinds of regional patterns in diffuse lung disease.

**METHOD AND MATERIALS**
HRCT images were selected from images of 106 patients having diffuse lung disease from a Siemens CT scanner (Sensation 16, Siemens, Forchheim, Germany) and 212 patients from a GE CT scanner (Lightspeed 16, GE, Milwaukee, WI, USA). Two experienced radiologists marked sets of 600 rectangular regions of interest (ROIs) with 20×20 pixels on HRCT images obtained from GE and Siemens scanners, respectively. These were consisted of a hundred of ROIs for each of six local patterns including normal, consolidation, emphysematous, ground-glass opacity, honeycombing, and reticular opacity (Fig. 1(a)). Performance of convolution neural network (CNN) classifier having a deep architecture (Fig. 1(b)) was compared with that of support vector machine (SVM) having a shallow architecture. In the SVM classifier, 22 features including histogram, gradient, run-length, gray level co-occurrence matrix, low-attenuation area cluster, and top-hat transform were extracted. In the CNN classifier, a hundred features in the last layer (FC #1), however, were extracted automatically with deep learning classifier manner. All experiments were performed based on forward feature selection and five fold cross-validation with 20 repetitions.

**RESULTS**
The accuracies of the SVM classifier were achieved 92.34 ± 2.26 % at 600 ROI images acquired in a single scanner (GE) and 91.18 ± 1.91 % at 1200 ROI images of the integrated data set (GE and Siemens). The accuracies of the CNN classifier showed a higher performance of 93.72 ± 1.95 % and 94.47 ± 1.19 % in a single and the integrated HRCT, respectively (Fig. 1(c)).

**CONCLUSION**
The SVM accuracy in the integrated data showed not inferior to that in a single vender data, due to the effect of different scanners. In the CNN classifier, however, the CNN performance in the integrated data might be better, due to more robustness to image noise and higher performance in larger data set. In addition, the CNN shows higher performance than the SVM in both of data types.

**CLINICAL RELEVANCE/APPLICATION**
Deep learning based automated quantification system of regional disease patterns at HRCT of interstitial lung diseases can be more useful in the diagnosis, severity assessment, and monitoring of treatment effects.

**SSA21-07 Predicting Radiologists’ Diagnostic Performances Using Quantitative Image Features: Preliminary Analysis**

**Participants**
Juhun Lee, PhD, Pittsburgh, PA (Presenter) Nothing to Disclose
Robert M. Nishikawa, PhD, Pittsburgh, PA (Abstract Co-Author) Royalties, Hologic, Inc;
Ingrid Reiser, PhD, Chicago, IL (Abstract Co-Author) Nothing to Disclose
John M. Boone, PhD, Sacramento, CA (Abstract Co-Author) Research Grant, Siemens AG Research Grant, Hologic, Inc Consultant, Varian Medical Systems, Inc

**PURPOSE**
The endpoint for assessing image quality should be related to radiologists' diagnostic performances, instead of imaging statistics, such as contrast to noise ratio. The purpose of this preliminary study is to evaluate breast computed tomography (CT) image quality using quantitative image features that are correlated with radiologists' diagnostic performances.

**METHOD AND MATERIALS**
A total of 102 pathology proven breast lesions in 92 dedicated breast CT images were used. An iterative image reconstruction (IIR) algorithm was used to obtain CT images with different image qualities (28 different qualities). Through image feature analysis from breast lesions (developing classifiers on image features from the lesion), two reconstruction options (i.e., 2 out of 28 different qualities) and one clinical reconstruction with area under the ROC curve (AUC) values of 0.67, 0.75, and 0.86 were selected for a reader study. A subset of breast lesions (N = 50, half malignant) were selected for the reader study. One experienced MQSA
radiologist read 150 cases (50 lesions x 3 image qualities) and reported each lesion’s probability of malignancy following BI-RADS. The radiologist’s performance was evaluated by measuring the AUC. Under leave-one-out-cross-validation, a logistic regression classifier was trained and tested over the image features (via a feature selection technique) and the probability of malignancy from the radiologist. The classifier’s AUC was measured and compared with that of the radiologist.

RESULTS
The radiologist’s AUCs for each quality were 0.74, 0.79, and 0.81. The trained classifier achieved averaged AUCs of 0.72, 0.76, and 0.77. The linear correlation coefficients between the radiologist’s probability and the radiologist’s probability on the test set were 0.51, 0.6, and 0.54 (all p-values < 0.001).

CONCLUSION
The classifier was able to learn the radiologist’s estimation of lesion malignancy. More readers are required to generalize our results.

CLINICAL RELEVANCE/APPLICATION
Quantitative image features were used to correlate radiologists’ diagnostic performances. These features may be useful for optimizing reconstruction algorithms and evaluating dose reduction techniques.

SSA21-08 Multivariate Modeling for Prediction of Cervical Cancer Treatment Outcomes

Sunday, Nov. 29 11:55AM - 12:05PM Location: S405AB

Participants
Baderaldeen A. Altazi, MS, Tampa, FL (Presenter) Nothing to Disclose
Daniel Fernandez, MD, PhD, Tampa, FL (Abstract Co-Author) Nothing to Disclose
Geoffrey Zhang, PhD, Tampa, FL (Abstract Co-Author) Nothing to Disclose
Eduardo G. Moros, PhD, MS, Tampa, FL (Abstract Co-Author) Nothing to Disclose

Background
Several studies reported univariate correlation analysis of radiomics as predictive factors for treatment clinical outcomes. This study investigated building a multivariate linear regression model that combines several predictive metrics in correlation with treatment outcomes.

Evaluation
Our dataset consisted of the pretreatment PET/CT scans from a cohort of 74 patients diagnosed with cervical cancer, FIGO stage IB-IIA, age range 31-76 years, treated with external beam radiation therapy to a dose range between 45-50.4 Gy (median dose: 45 Gy), concurrent cisplatin chemotherapy and MRI-based Brachytherapy to a dose of 20-30 Gy (median total dose: 28 Gy). Pearson’s correlation (PC) and Area under (AUC) the receiver operator curve (ROC) were used to assess the correlation with treatment outcomes. Radiomics features were extracted; Co-occurrence (COM), Gray Level Size Zone (GLSZ) and Run Length (RLM) and Intensity Based (IBM) Matrices algorithms. Afterwards, they were selected using sequential backward selection to predict for distant metastases (DM), Locoregional recurrence (LRR) and last follow-up status (LFS).

Discussion
The models consisted of linear combination of 2 to 3 radiomics features for each outcome. LRR model consisted of (Intensity contrast and Low Gray-Level Run Emphasis). LFS model consisted of (Different Entropy, Intensity contrast and Low-Intensity small-area emphasis). DM models consisted of (size zone variability and small-area emphasis) and (surface/Area and Volume). Models showed PC scores range (0.3-0.5) and AUC range (0.75-0.9) with 95% CI (0.6-1.0). All models scored low Variance Inflation Factor (VIF < 5) based on multicolinearity diagnostics test. All tests were statistically significant (p<0.05).

Conclusion
Multivariate linear regression models of radiomics features improved prediction power of treatment outcomes in comparison to univariate analysis. Moreover, all models passed multicolinearity diagnostics test. LRR model scored highest improved predictive power followed by LFU then DM models respectively. This approach may contribute to incorporate PET radiomics in patient’s response analysis in clinic.

SSA21-09 Increasing the Interscan Reproducibility of Coronary Calcium Scoring by Partial Volume Correction in Low-Dose non-ECG Synchronized CT: Phantom Study

Sunday, Nov. 29 12:05PM - 12:15PM Location: S405AB

Pim A. De Jong, MD, PhD, Utrecht, Netherlands (Abstract Co-Author) Nothing to Disclose
Ivana Isgum, PhD, Utrecht, Netherlands (Abstract Co-Author) Research Grant, Pie Medical Imaging BV; Research Grant, 3mensio Medical Imaging BV;

PURPOSE
Coronary calcium (CAC) scores obtained in low-dose chest CT without ECG-synchronization, as acquired in lung cancer screenings, are strong and independent predictors of cardiovascular events (CVE). However, due to acquisition, interscan CAC score reproducibility is moderate. This may result in incorrect CVE risk prediction. To increase the interscan reproducibility of CAC scores, we have developed a method to quantify CAC using partial volume correction (PVC).

METHOD AND MATERIALS
Three phantoms were scanned (Philips Brilliance 64, 120 kVp, 20 mAs, 3.0 mm slice thickness, 3.0 mm increment), each containing 3 inserts differing in size (9.1, 24.6 and 62.8 mm³) and calcium density (0.197, 0.401 and 0.796 mg/mm³). Total CAC volume per scan
was 96.5 mm³. Each phantom was scanned 3 times with slight rotation and translation between acquisitions, and in 3 different scenarios: 1 stationary and 2 moving with speed of 10 mm/s and 30 mm/s without ECG-synchronization, resulting in total of 27 scans. CAC was scored by clinically used thresholding at 130 HU. Thereafter, PVC employing Expectation-maximization algorithm for learning a multi-dimensional Gaussian mixture was used to determine partial content of calcium in the voxels of each identified calcification and its vicinity. The total CAC volumes per scan were computed by thresholding and using the proposed PVC method.

RESULTS
For the stationary phantom with low, medium and high density inserts, thresholding resulted in CAC volumes of 60.9, 142.9 and 213.2 mm³, while PVC determined 70.4, 88.9 and 92.9 mm³, respectively. For the phantom moving at 10 mm/s, thresholding resulted in CAC volumes of 50.3, 149.8 and 224.6 mm³, while PVC gave 58.2, 91.2 and 96.7 mm³, respectively. For the phantom moving at 30 mm/s, thresholding resulted in CAC volumes of 15.1, 147.2, and 306.3 mm³ and PVC determined 51.8, 78.8 and 106.5 mm³, respectively.

CONCLUSION
Thresholding underestimates volume of low density and overestimates volume of high density calcifications. The effect is emphasized with increasing motion artefacts. PVC provides better estimates of true calcium volume and it is less affected by motion.

CLINICAL RELEVANCE/APPLICATION
CAC quantification using PVC may increase interscan reproducibility of the CAC volume score.
**Cardiac (Dual-energy Cardiac CT)**

**PURPOSE**
To assess the gatekeeper function of one-stop-shop cardiac dual-energy CT (DECT) in acute myocardial infarction (AMI) patients to avoid unnecessary invasive coronary angiography (ICA), by evaluating its diagnostic performance to detect coronary stenoses, myocardial perfusion defects, and myocardial infarction, using ICA plus 13N-ammonia/18F-deoxyglucose (FDG) PET as the gold standard.

**METHOD AND MATERIALS**
Consecutive AMI patients scheduled for ICA who have not undergone primary or rescue angioplasty were prospectively recruited. One-stop-shop DECT and 13N-ammonia/18F-FDG PET were undergone before ICA. The one-stop-shop DECT needed a dual-phase scan. First phase was scanned in arterial phase, used to reconstruct images of DECT angiography (DE-CTA) and DECT myocardial perfusion (DE-CTP). Second phase was delayed phase DECT which was scanned 10 seconds after first phase scan, used to detect myocardial infarction. Image analysis was as follow: firstly, identify the area of myocardial perfusion defects and myocardial infarction by DE-CTP and delayed phase DECT using 13N-ammonia/18F-FDG PET as the gold standard. A concordant reduction in 13N-ammonia perfusion PET and 18F-FDG metabolic PET (matching defects) indicates myocardial infarction. Then assess the presence or severity of stenoses on coronary artery supplying area of myocardial perfusion defects or myocardial infarction by DE-CTA, using ICA as the gold standard. If there were multiple plaques in coronary, the lesion with larger plaque area was considered as the culprit lesion. Significant stenosis was defined as a luminal diameter reduction of ≥50% on coronary artery.

**RESULTS**
A total of 25 patients were successfully completed one-stop-shop DECT, 13N-ammonia/18F-FDG PET and ICA. Intervals between examinations were no more than 1 week. ICA plus 13N-ammonia/18F-FDG PET showed 20 AMI patients with significant stenoses on IRA. One-stop-shop DECT correctly identified 20 AMI patients with significant stenoses on IRA (sensitivity 100%) and correctly ruled out 5 patients AMI (specificity 100%).

**CONCLUSION**
One-stop-shop cardiac DECT has a gatekeeper function to avoid unnecessary ICA in patients early after AMI without significant stenosis.

**CLINICAL RELEVANCE/APPLICATION**
One-stop-shop cardiac DECT has a gatekeeper function to avoid unnecessary ICA in patients early after AMI without significant stenosis.
The purpose of this study was to evaluate the usefulness of myocardial extracellular volume fraction (ECV) from iodine density image using ssDECT by comparison with subtraction derived ECV.

**METHOD AND MATERIALS**

SsDECT image was collected from patients suspected of coronary artery disease or further evaluation of reducing ejection fraction. All subjects were performed non-contrast and equilibrium contrast-enhanced CT using ssDECT. Manually-measured ECV (mECV), automatically-subtracted ECV using non-rigid deformation (nECV) and equilibrium-iodine density derived ECV (iECV) using iodine density image without subtraction were calculated on the mid-left ventricular level. mECV, nECV and iECV were compared by using Pearson correlation. Agreements among three methods were assessed by using Bland-Altman comparison.

**RESULTS**

Twenty-two patients were evaluated. iECV was calculated without plain CT. The correlations of each ECV measurement approach were as follows: (mECV and iECV; r=0.754, p<0.001), (mECV and nECV; r=0.623, p=0.002). ECV was higher in patients with heart failure than healthy control subjects for mECV (30.73 vs. 24.45, p=0.012), nECV (30.60 vs. 24.95, p=0.027) and iECV (29.79 vs. 24.68, p=0.007). Mean radiation dose was 3.5±0.2mSv for each CT acquisition.

**CONCLUSION**

ECV using iodine density image correlates with ECV calculated by subtraction, which allows for the noninvasive quantitative quantification of the diffuse fibrosis burden in myocardial diseases with less radiation dose and without plain CT.

**CLINICAL RELEVANCE/APPLICATION**

ECV derived from Iodine density image using ssDECT enables measurement of ECV without non-enhanced CT and discriminate patient increased ECV as well as subtraction derived ECV. This approach leads to reduction of X-ray exposure.

**SSA02-03 Underestimation of Atherosclerotic Burden by Invasive Coronary Angiography Compared to Dual Energy Computed Tomography**

Sunday, Nov. 29 11:05AM - 11:15AM Location: S502AB

**Participants**

Gaston Rodríguez Granillo, Vicente Lopez, Argentina (Abstract Co-Author) Nothing to Disclose
Patricia M. Carrascosa, MD, Buenos Aires, Argentina (Presenter) Research Consultant, General Electric Company
Alejandro Deviggiano, MD, Vicente Lopez, Argentina (Abstract Co-Author) Nothing to Disclose
Carlos Capunay, MD, Buenos Aires, Argentina (Abstract Co-Author) Nothing to Disclose
Macarena De Zan, Vicente Lopez, Argentina (Abstract Co-Author) Nothing to Disclose
Alejandro Goldsmith, MD, Buenos Aires, Argentina (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

Dual energy (DE) CTCA has emerged as a novel approach that aims to convey a more accurate assessment of atherosclerotic coronary plaques since it attenuates some of the limitations related to the polychromatic nature of x-rays, by means of synthesized monochromatic evaluation. We sought to explore the differences between atherosclerotic burden with invasive coronary angiography (ICA) and DE-CTCA in symptomatic patients.

**METHOD AND MATERIALS**

The present prospective study involved patients with suspected coronary artery disease (CAD) referred for invasive coronary angiography (ICA). Patients were categorized according to the atherosclerotic burden extent using the modified Duke prognostic CAD index, the CAD extension score, and the segment stenosis score (SSS), which reflect the extension and severity of the atherosclerotic burden; and the segment involvement score (SIS), which only reflects the extent of the atherosclerotic burden.

**RESULTS**

Eighty patients were prospectively included in the study protocol. The mean age was 62.0±10.9 years, and 59 (74 %) patients were male. The mean SIS (8.2±3.9 vs. 6.0±3.7, p<0.0001), modified Duke index (4.33±1.6 vs. 4.0±1.7, p=0.003), the CAD extension score (4.8±4.1 vs. 4.4±2.1, p=0.005), and the median SSS (13.5 (9.0-18.0) vs. 9.5 (5.0-15.0), p<0.0001) were significantly higher at DE-CTCA compared to ICA. DE-CTCA showed a significantly higher number of patients with any left main coronary artery lesion (46 (58 %) vs. 18 (23 %), p<0.0001) and with severe proximal lesions (0.28±0.03 vs. 0.26±0.03, p<0.0001) than ICA. Overall, DE-CTCA identified a larger extent of disease at proximal and mid coronary segments compared to ICA, particularly higher at the left main coronary artery (DE-CTCA 0.69±0.7 vs. ICA 0.29±0.6, p<0.0001).

**CONCLUSION**

In this study, CTCA using dual energy imaging identified a significantly larger atherosclerotic burden compared to ICA, particularly involving the proximal segments. Our findings provide further insights into the limitations of ICA and the concept of normal or near normal coronary arteries, although the potential clinical implications should be explored in further prospective natural history studies.

**CLINICAL RELEVANCE/APPLICATION**

Dual energy (DE) CTCA has emerged as a novel approach that aims to convey a more accurate assessment of atherosclerotic coronary plaques since it attenuates some of the limitations related to the polychromatic nature of x-rays.

**SSA02-04 First Experience of Monochromatic Energy Level of Newly Generation of Spectral CT Associated with Regard to Energy Computed Tomography**

**PURPOSE**

The purpose of this study was to evaluate the usefulness of myocardial extracellular volume fraction (ECV) from iodine density image using ssDECT by comparison with subtraction derived ECV.

**METHOD AND MATERIALS**

SsDECT image was collected from patients suspected of coronary artery disease or further evaluation of reducing ejection fraction. All subjects were performed non-contrast and equilibrium contrast-enhanced CT using ssDECT. Manually-measured ECV (mECV), automatically-subtracted ECV using non-rigid deformation (nECV) and equilibrium-iodine density derived ECV (iECV) using iodine density image without subtraction were calculated on the mid-left ventricular level. mECV, nECV and iECV were compared by using Pearson correlation. Agreements among three methods were assessed by using Bland-Altman comparison.

**RESULTS**

Twenty-two patients were evaluated. iECV was calculated without plain CT. The correlations of each ECV measurement approach were as follows: (mECV and iECV; r=0.754, p<0.001), (mECV and nECV; r=0.623, p=0.002). ECV was higher in patients with heart failure than healthy control subjects for mECV (30.73 vs. 24.45, p=0.012), nECV (30.60 vs. 24.95, p=0.027) and iECV (29.79 vs. 24.68, p=0.007). Mean radiation dose was 3.5±0.2mSv for each CT acquisition.

**CONCLUSION**

ECV using iodine density image correlates with ECV calculated by subtraction, which allows for the noninvasive technique quantification of the diffuse fibrosis burden in myocardial diseases with less radiation dose and without plain CT.
Lower Contrast Agent Dose 200mgI/kg on Coronary Artery Imaging

Sunday, Nov. 29 11:15AM - 11:25AM Location: S502AB

Participants
Zha Kajii, Zhengzhou, China (Presenter) Nothing to Disclose

PURPOSE
To investigate the feasibility of newly generation of spectral CT associated with low contrast agent dose of 200mgI/kg in coronary CT angiography (CCTA) and the optimal monochromatic energy level of newly generation of spectral CT compared with conventional 120kVp scan.

METHOD AND MATERIALS
58 patients with suspected coronary heart disease underwent CCTA on a newly generation of spectral CT scanner (Discovery CT, GE healthcare). According to heart rate, the patients were divided into 2 groups: retrospectively ECG triggered CCTA(HR>70)in Group A(n=30) with CM volume of 300mgI/kg and prospective ECG triggered CCTA (HR<70)in Group B(n=28) with CM volume of 200mgI/kg . The CM injection rate was calculated as volume divided by 12 seconds for both groups. Monochromatic images from 60 to 80 kev with increment of 5 kev were obtained (B1-B5) and with a fixed blending level of ASIR for each image set. CT values , image noise , signal-to-noise ratio(SNR) and contrast-to-noise ratio(CNR) of the left main coronary artery , proximal segment of left anterior descending branch, proximal segment of left circumflex branch and proximal segment of right coronary artery of group A and group B1-B5. The results were compared with one way ANOVA.

RESULTS
There was no significant difference on CNR of coronary artery images between groups B1-B5 [(17.1±4.4),(17.5±3.0),(16.8±4.0), (16.3±4.2),(16.5±3.5)] and group A(16.6±4.8). There was no significant differences among groups B1- B4 (P>0.05). CT values of the vessels from groupB1-B5 were (331.4±40.2) , (351.7±59.3), (320.1±41.8) , (330.0±40.5) , (301.4±45.6)HU, respectively. Compared with 120kVp scan, 65keV images had equivalent CT values of the vessels(351.7±59.3HU versus 361.7±59.3HU, P >0.05) and lower image noise (26.8±4.3HU versus(31.1±9.9), P<0.01).

CONCLUSION
Spectral CT associated with low contrast agent dose of 200mgI/kg in CCTA and monochromatic images of 65keV can provide better image quality than the conventional 120kVp scan.

CLINICAL RELEVANCE/APPLICATION
These results suggest a possibility of low contrast agent dose of 200mgI/kg from cardiac spectral CT with monochromatic images of 65keV can provide better image quality.

SSA02-05 Quantitative Evaluation of Beam-Hardening Artefact Correction at Dual-Energy CT Myocardial Perfusion Imaging

PURPOSE
To quantitatively assess the impact of a novel reconstruction algorithm ("kernel D33f") with beam-hardening correction (BHC) on beam-hardening artefacts of the myocardium at dual-energy computed tomography myocardial perfusion imaging (DE-CTMPI).

METHOD AND MATERIALS
Rest-series of DE-CTMPI studies from 14 patients were retrospectively analyzed. Six image series were reconstructed for each patient using 3.0 mm section thickness: a) 100kV, b) 140kV, and c) linearly-blended MIX0.5, each with BHC (D33f kernel) and without (D30f). A total of 756 myocardial regions were analyzed. Seven regions of interest (ROI) equally subdivided the myocardium in the axial section. Three subdivisions were made within areas prone to BHA. Reports of SPECT studies within 30 days of CT examination were used to confirm presence and location of true perfusion defects. The relative difference of ROI attenuation from average myocardial attenuation (RDTM) was determined as an indicator for homogeneity of myocardial attenuation. Paired student t-test was used for statistical evaluation.

RESULTS
Overall mean myocardial attenuation was lower on corrected reconstructions (D30f, 87.3±24.1 HU; D33f, 85.5±21.5 HU, p=0.009). Overall RDTM was more homogeneous using BHC (D30f, -0.3±11.4%; D33f, 0.1%±10.1% p<0.001). Changes in RDTM were greatest in the postero-basal myocardium (D30f, -16.2±10.0%; D33f, 3.4±10.7%; p<0.001).

CONCLUSION
A dedicated reconstruction algorithm with BHC can significantly reduce beam-hardening artefacts at DE-CTMPI to improve the specificity of myocardial perfusion defect assessment.
**Diagnostic Value of Spectral CT Combined with Serum Biomarkers in Determining Coronary Artery Plaque Characteristics—A Preliminary Study**

Sunday, Nov. 29 11:35AM - 11:45AM Location: S502AB

**Participants**
Huang Renjun, Suzhou, China (Presenter) Nothing to Disclose
Dai Hui, Wuhan, China (Abstract Co-Author) Nothing to Disclose
Li Yonggang, Suzhou, China (Abstract Co-Author) Nothing to Disclose
Guo Liang, Suzhou, China (Abstract Co-Author) Nothing to Disclose

**PURPOSE**
The aim of the present study was to evaluate the value of spectral computed tomography (CT) in determining coronary plaque composition and in reflecting coronary plaque vulnerability which were compared with CT values and the findings of serum biomarkers as the reference standard.

**METHOD AND MATERIALS**
107 consecutive patients (65 males and 42 females) underwent coronary CTA on a GSI capable 64-slice CT scanner. Plaques were divided into 5 groups according to MSCT criteria (plaque density expressed by Hounsfield units [HU]) and the size of calcification in mixed plaques. Spectral curve and effective atomic number and two-material decomposition (FAT and HAP) technique were used to analyze coronary plaques. The vulnerability of plaques was determined by serum biomarkers including soluble OX40 ligand (sOX40L) and matrix metalloproteinases (MMP-9) and lipoprotein associated phospholipase A2 (Lp-PLA2). The concentration of serum biomarkers were measured by ELISA.

**RESULTS**
159 coronary artery plaques were analyzed. 90 cases of blood samples were obtained, and 42 cases were negative on CT. By measuring CT values, the plaques were classified as fibrous (group 1, n=29), which had a density of 61-129 HU (75±20 HU), soft (group 2, n=35), which had a density of ≤60 HU (36±30 HU), and calcified (group 3, n=24), which had a density of ≥130 HU (774±234 HU). Mixed plaques with larger (group 4, n=40, 465±196 HU) or spotty (group 5, n=31, 53±32 HU) calcification were also analyzed. Except the value of FAT between group 1 and group 5 and between group 2 and group 5, there were statistically significant differences of four spectral results among the 4 groups (p<0.05). Levels of three serum biomarkers were significantly higher in positive patients (p<0.05). There were significant differences of MMP-9 levels between group 2 and group 3 (p<0.05). Negative correlations were found between serum MMP-9 levels and CT density (r=-0.501, p<0.05) and effective atomic number (r=-0.372, p<0.05) and slope of spectral curves (r=-0.378, p<0.05) and value of HAP (r=-0.411, p<0.05).

**CONCLUSION**
Our results indicate that spectral CT might be used to differentiate atherosclerotic plaques. Serum levels of sOX40L and MMP-9 and Lp-PLA2 correlate with the coronary atherosclerosis, and the elevated levels of MMP-9 might be associated with coronary plaque vulnerability.

**Performance Evaluation of Virtual Un-enhanced CT Images from Spectral CT Coronary Artery Angiography: Potential Feasibility of Replacing Routine Calcium Scoring Scan**

**Participants**
Zha Kaiji, Zhengzhou, China (Presenter) Nothing to Disclose

**PURPOSE**
To evaluate the image quality and calcium score accuracy in patients with atherosclerotic plaques by comparing virtual unenhanced (VU) CT images generated from cardiac spectral CT with conventional calcium score scan (CS).

**METHOD AND MATERIALS**
Fifty-eight patients (58 ± 11 years, 38 men) with Coronary atherosclerotic plaques underwent CCTA exams on a newly generation spectral CT scanner (Discovery CT, GE healthcare). It included conventional 120kVp scan for calcium scoring (CS) and coronary artery imaging using spectral CT with GSI mode. The virtual un-enhanced CT (VU) images were reconstructed based on the enhanced spectral CT imaging data set of 70 keV. Calcium scores values were computed and compared between two groups. Results were compared vis-a-vis absolute calcium score values, age-, gender- and race-dependent percentiles, and commonly used calcium score risk classification categories.

**RESULTS**
There was no significant difference on Agatston calcium score values between VU images and CS images (245.6±430.5 vs 262.0±499.5; P>0.05). There was high correlation between Calcium score risk categories and Multi-Ethnic Study of Atherosclerosis (MESA) percentiles (Spearman rank correlation coefficient?=0.97, P?). Calcium score values of virtual unenhanced images derived from gemstone spectral imaging (GSI) were highly correlated with conventional unenhanced CT calcium scoring images.

**CLINICAL RELEVANCE/APPLICATION**
Spectral CT might be used to differentiate atherosclerotic plaques and indicate coronary plaque vulnerability.
These results suggest a possibility of radiation dose and time-saving when omitting calcium scores scan from CCTA exams by using virtual unenhanced images.

**SSA02-08 Improvement of Image Quality Using Adaptive Statistical Iterative Reconstruction in the Evaluation of Chronic Myocardial Infarction Using Iodine Density Image with Spectral CT**

Sunday, Nov. 29 11:55AM - 12:05PM Location: S502AB

Participants
- Junichi Kishimoto, Yonago, Japan (Presenter) Nothing to Disclose
- Yasutoshi Ohta, MD, Yonago, Japan (Abstract Co-Author) Nothing to Disclose
- Shinichiro Kitao, Yonago, Japan (Abstract Co-Author) Nothing to Disclose
- Tomomi Watanabe, MD, Yonago, Japan (Abstract Co-Author) Nothing to Disclose
- Toshihide Ogawa, MD, Yonago, Japan (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

The aim of this study was to evaluate the effect and determine the optimal blend percentages of adaptive statistical iterative reconstruction (ASiR) for iodine density imaging (IDI) of myocardial late iodine enhancement (LIE) in the evaluation of chronic myocardial infarction (CMI) with spectral CT.

**METHOD AND MATERIALS**

A total of 28 patients underwent cardiac LIE using a single source dual-energy CT scanner (DiscoveryCT 750HD, Freedom Edition: GE). IDI between 0% and 100% of contributions of ASiR in 10% increments were reconstructed. The signal-to-noise ratio (SNR) of remote myocardium and the contrast-to-noise ratio (CNR) of infarcted myocardium were measured. Transmural extent of infarction was graded by using a 5-point scale (0= no late enhancement, 1= late enhancement with 1-24% of transmural extent, 2= 25-49%, 3= 50-74%, 4= 75-100%). The SNR, CNR, and transmural extent were assessed in a contribution ratio of each ASiR. The transmural extents were compared with MRI as a reference standard.

**RESULTS**

In comparison with 0% ASiR, the use of 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80%, and 100% ASiR resulted in reduction of image noise between groups (-5.4%, -12.9%, -20.3%, -26.9%, -34.0%, -41.3%, -47.6%, -54.0%, -60.1% and -64.8%, respectively; p<0.01) without difference in signal (p=NS). Compared with 0% ASiR images, reconstruction with 100% ASiR image demonstrated the highest improvement in SNR (229%; p<0.001) and CNR (199%; p<0.001). 80%-100% ASiR demonstrated the highest ratio (73.7%) of accurate transmural extent classification in comparison to MRI.

**CONCLUSION**

ASiR intensity of 80% to 100% improves image quality without changes in signal and maximizes the accuracy of transmural extent in infarcted myocardium.

**CLINICAL RELEVANCE/APPLICATION**

Use of ASiR improves the image quality of LIE on iodine density image and leads to accurate diagnosis of transmural extent.

**SSA02-09 Reduction of Coronary Motion Artifact in Monochromatic Imaging at Various Energy Levels Using a Motion Correction Algorithm in ECG-gated Single-source Dual-Energy Coronary CT Angiography with Rapid Switching of the Tube Voltage: Clinical Impact**

Sunday, Nov. 29 12:05PM - 12:15PM Location: S502AB

Participants
- Rika Fukui, Tokyo, Japan (Presenter) Nothing to Disclose
- Jianbo Gao, MD, Zhengzhou, China (Abstract Co-Author) Nothing to Disclose

- Isao Tanaka, Tokyo, Japan (Abstract Co-Author) Nothing to Disclose
- Takuya Ishikawa, Tokyo, Japan (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To investigate the clinical impact of reduction of coronary motion artifact in monochromatic imaging (MI) at various energy levels obtained using a motion correction algorithm (MCA) in electrocardiography-gated single-source dual-energy coronary computed tomography angiography with rapid switching of the tube voltage (DECTA).

**METHOD AND MATERIALS**

We retrospectively assessed 134 consecutive patients (73 men; mean age 68 ± 11 years; mean heart rate 53.7 ± 5.0 bpm) who underwent DECTA. On 65-keV MI reconstructed at the optimal cardiac phase without the MCA using the detail kernel, adaptive statistical iterative reconstruction algorithm (50% blending ratio), and 20-cm field of view, 3 readers independently graded per-vessel coronary motion artifact from one (poor) to 5 (excellent) (3 to 5, interpretable) for the right (#one to 3) and left coronary arteries (#5 to 8) and left circumflex artery (#11, 13). For 30 uninterpretable vessels in 24 of 134 patients, MI was reconstructed at 45 to 105 keV at 20-keV intervals with the MCA; the readers regraded per-vessel coronary motion artifact on the MI; and the percentage of interpretable vessels achieved with the MCA was calculated at each energy level. We compared grades between images obtained with and without the MCA using Wilcoxon signed-rank test and for each energy level with the MCA using Kruskal-Wallis test.

**RESULTS**

For the 30 vessels in 24 patients that were uninterpretable without the MCA, 26 (87%) at 45 and 65 keV, 21 (70%) at 85 keV; and 16 (53%) at 105 keV were interpretable with the MCA. Grades of coronary motion artifact were 1.6 ± 0.5 at 65 keV without the
MCA and $3.7 \pm 1.0$ at 45 keV, $3.6 \pm 1.0$ at 65 keV, $3.1 \pm 1.1$ at 85 keV, and $2.8 \pm 1.2$ at 105 keV with the MCA. Grades were significantly better with the MCA than without at any energy level ($P < 0.01$ for all), and the grade with the MCA between any 2 energy levels ($P > 0.05$) differed significantly only between 45 and 105 keV.

**CONCLUSION**

Use of the MCA on MI at 45 to 65 keV is clinically useful for reducing coronary motion artifact in DECCTA.

**CLINICAL RELEVANCE/APPLICATION**

Use of the MCA for MI at a lower keV is clinically useful to reduce coronary motion artifact and improve image interpretability and diagnostic accuracy in DE CCTA.

SSA11-02 Virtual Reality Training Modules Hold Potential for IR Education

Participants
Colin J. McCarthy, MD, Boston, MA (Presenter) Nothing to Disclose
Alvin Y. Yu, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose
Stephen R. Lee, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose
Synho Do, PhD, Boston, MA (Abstract Co-Author) Nothing to Disclose
Steven L. Dawson, MD, Cambridge, MA (Abstract Co-Author) Consultant, Cook Group Incorporated Royalties, CAE Healthcare, Inc
Raul N. Uppot, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose

Background
The challenge for all types of interventional radiology (IR) training is hands-on experience. Currently, IR trainees learn procedures by watching and assisting in cases. We set out to develop and evaluate an immersive virtual reality (VR) simulator, the aim of which was to provide trainees with an introduction to IR procedures. These modules differ from traditional textbooks or online learning sites, since they immerse the participant in the center of activity. Advances in the VR field have allowed for not only realistic display of stereoscopic and 360-degree images, but also the recording of such immersive content.

Evaluation
An introductory IR tutorial was recorded using a dual camera system (GoPro, Inc.) and post-processed to generate a stereoscopic 3D tutorial. The content was displayed using a head-mounted VR headset, featuring low-latency gyroscope paired with two low persistence OLED displays located immediately in front of the viewer's eyes, blocking out all external visual stimuli (Oculus VR, LLC). Additional tutorials were also constructed from a 7 camera rig (360Heros, Inc.) that captured 360-degree environmental images, allowing full immersion in the IR suite. Footage from 7 individual cameras was fused and synchronized using software (Autopano Video, Kolor SARL). Participants were asked to complete a survey after the tutorial, with questions designed around a Likert scale.

Discussion
12 participants agreed to partake in the study, 6 Attending Radiologists, 5 Fellows and 1 Resident. 75% (n = 9) of those surveyed felt that the immersive VR training module was “good” or “excellent”. All participants felt that the VR headset had potential to improve IR training in the future. Feedback included some reports of initial motion sickness, potential to interact with the 3D environment and the need to incorporate radiology images into the interactive content.

Conclusion
Immersive VR platforms hold potential to enhance education in Interventional Radiology. The technology is in its early stages, but may serve as an adjunct to existing methods of training. In addition to stereoscopic 3D tutorials, interactive 360-degree video content may prove valuable to those unfamiliar with an interventional suite.

SSA11-03 Teaching File 2.0: The Next Generation of Radiology Education with Open Web Technologies

Participants
Jason M. Hostetter, MD, Baltimore, MD (Presenter) Nothing to Disclose
Christopher Trimble, MD, MBA, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Michael A. Morris, MD, MS, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Jean Jeduy Jr, MD, Baltimore, MD (Abstract Co-Author) Nothing to Disclose

Background
Radiology education has long consisted of static images displayed alongside text, often in powerpoint slides or textbooks. This
Presentation style is incongruent with the modern radiologist's digital, interactive workflow. Our project aims to allow radiologists to easily create interactive, anonymized, standards compliant teaching files, available anywhere, on any device.

**Evaluation**

Using standard web technologies of HTML5 and JavaScript, we created a cloud-based application to create and store radiology cases. Integrated with our enterprise PACS via DICOM standards, studies are fully anonymized with one click, creating a web-based teaching case that is always-on, shareable, and available to desktop PCs, tablet devices, and modern smartphones without installing third party software. Similar to normal web pages, cases can be manipulated with hyperlinks in case descriptions or in other web pages in which the case is displayed. Cases are viewed in a web browser with full DICOM support allowing a true PACS environment. The application has been used at our institution over the past year to create educational modules for medical students as well as to create interactive educational e-books about radiology and pathology topics. Residents and faculty also utilize the system to maintain personal case logs and share interesting cases via email or text within HIPAA compliance.

**Discussion**

Our implementation brings full PACS functionality to a portable and extensible educational platform. By utilizing existing web and DICOM standards, any device with a modern web browser is a fully enabled DICOM viewer, and any standards compliant PACS can be easily integrated to generate anonymized cases in a single click. A cloud based solution also allows easy sharing and collaboration, by simply sending a link via email, text, or social media, in same way one may share an interesting article. Our architecture eliminates the need for local archival storage, ensuring cases are always instantly available.

**Conclusion**

We created a cloud based radiology educational resource using standard web technologies, with full PACS functionality, and automated anonymization to bring radiology educational materials to the modern web.

**SSA11-04 Simultaneous Human-Readable and Structured Data Encoding from PDF Forms**

**Sunday, Nov. 29 11:15AM - 11:25AM Location: S403A**

**Participants**
- Zachary S. Delproposto, MD, Detroit, MI (Presenter) Nothing to Disclose
- Matthew C. Rheinboldt, MD, New Orleans, LA (Abstract Co-Author) Nothing to Disclose

**Background**

Clinical and research needs often demand the need to store metadata which is not integral to the EHR (e.g., RECIST data). While PDF files can be saved as DICOM images, structure is lost and maintained only by entry into a separate system which requires maintenance and dissociates captured information from the study data. We have created a system to extract data from PDF Forms and simultaneously embed the form itself as a human-readable DICOM image, and the structured form data as an embedded QR code within a DICOM image.

**Evaluation**

Using PDF forms eliminates the need for custom local or web applications to edit structured data. Storing the PDF data as an image allows for facile retrieval of human-readable information sans additional software. QR-encoded structured data is stored as DICOM image data, not using private/non-standard fields, maintaining superb vendor neutrality and compatibility. QR-codes also permit structured data capture directly into mobile applications. Leveraging existing PACS infrastructure obviates the need for an external database. Extraction of structured data and PDF form re-creation occurs as needed; the presence of image-embedded structured data does not diminish the performance of the PACS or impede interpretation of diagnostic data.

**Discussion**

Built using open-source components and leveraging the existing PACS infrastructure, we find that our system allows easy, reliable metadata entry and recall (Figure 1). Since forms are stored both as a PDF image and as QR-encoded structured data image, workstations without the need for structured metadata entry or recall function normally without workflow impact. Most users are familiar with PDF forms, which are in common use and routinely used at both public and private institutions. PDF forms can be constructed to constrain input fields to appropriate types (e.g., numeric fields), enforcing data consistency. Ease of use is a key factor in this system. Additional data storage requirements are minimal, adding only a few images to each study.

**Conclusion**

We show a robust, efficient, cost-effective method to encode metadata from PDF forms simultaneously in a human-readable image and machine readable structured image formats.

**SSA11-05 Call Cases Dashboard: What a First-Year Radiology Resident Knows before Call**

**Sunday, Nov. 29 11:25AM - 11:35AM Location: S403A**

**Participants**
- Linda Kelahan, MD, Washington, DC (Presenter) Nothing to Disclose
- Allan Fong, BS, MS, Washington, DC (Abstract Co-Author) Nothing to Disclose
- Raj Ratwani, Washington, DC (Abstract Co-Author) Nothing to Disclose
- Ross W. Filice, MD, Washington, DC (Abstract Co-Author) Nothing to Disclose

**Background**

Current ACGME guidelines do not help first-year radiology residents prepare for the daunting task of taking call. Tracking exposure to high-acuity cases that are likely to be encountered while taking call can provide a framework for focused study and reflection. Furthermore, these cases can subsequently be utilized for educational or research purposes.

**Evaluation**

We focused on cases most likely to be encountered in a resident call setting. First, we limited evaluation to relevant procedures (i.e., CT abdomen/pelvis for appendicitis). We then applied natural language processing (NLP) techniques (specifically sentence
RESULTS of one-way ANOVA.

Invitations had been announced and 2) Saturday morning after the meeting had concluded. Data analysis was performed by means

### Discussion

Current methods of assessing resident progress, such as ACGME case log minimums, do not elucidate the types of pathology the
resident sees nor the decisions the resident should make. Our model attempts to both highlight cases that have important call-
relevant pathology but also negative cases where that pathology should be considered (i.e. CT for right lower quadrant pain). By
making this data available to our residents, we believe they will better understand how prepared they are for call, will have
opportunity to further educate themselves if needed, and will hopefully improve their receiver operating characteristic (ROC) on
call, which would positively impact clinical care. Furthermore, we are developing a repository of important call cases for any
resident could review for educational or research purposes.

### Conclusion

Our "call cases" dashboard has multiple advantages to traditional CPT-code driven analysis of radiology resident education. We can
identify positive high acuity call-relevant studies viewed prior to beginning call, but also negative cases where there was high
clinical suspicion. Furthermore, this repository allows residents to review call-relevant cases for educational or research purposes.

**SSA11-06  Resident Performance Analytics Using Structured Attending Feedback and #Hashtag Sharing Features**

*Sunday, Nov. 29 11:35AM - 11:45AM Location: S403A*

**Participants**

Po-Hao Chen, MD, MBA, Philadelphia, PA (Presenter) Nothing to Disclose
Yin J. Chen, MD, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose
Mary H. Scanlon, MD, FACC, Haverford, PA (Abstract Co-Author) Nothing to Disclose
Tessa S. Cook, MD, PhD, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose

**Background**

The qualitative evaluation of a trainee's a radiology interpretation is an important dimension of training that is difficult to
meaningfully analyze and quantify. We previously presented an open-source web-based platform that provided volume-related
analytics for residents. Working from the existing code, we added visualization of attending feedback on resident reports, analytics
of qualitative grading of on-call studies, and social media features allowing annotation and sharing of interesting cases.

**Evaluation**

Building upon our open-source software, we implemented new functionality for analyzing attending modifications on both daytime
and off-hour preliminary interpretations. At our institution, attending radiologists grade independently-interpreted, on-call exams
using a 5-point scale: 'Great Call,' 'Agree,' 'Addition,' 'Minor Change,' and 'Major Change.' After loggin in, the software analyzes the
trainee user's attending grades and offers birds' eye view of discrepancy rates, turnaround times, and volume of call studies. The
data can be organized by modality and anatomy. For each study, the software offers a 'Show Changes' view to highlight attending
edits on preliminary reports. An administrators' view is available for residency and fellowship directors. The trainee and
administrators may annotate each examination using free text, or apply social media-like #hashtags for sharing. We tracked
trainees' usage of the software before and after new feature implementation.

**Discussion**

Analysis of usage patterns during the three months post-implementation (9/1/2014-11/30/2014) showed 494 distinct user logins per
month, compared to 142 per month in the preceding three months (5/1/2014-7/31/2014) when these new features were not
available. Additionally, 86 unique tags have been created by users with 962 total applications as of 2/28/2015. Some uses for
hashtags include teaching ('#RareDx'), follow-up ('#FollowUp'), and documenting interpretive errors ('#SatOfSearch').

**Conclusion**

Implementation of new qualitative analytic and sharing features have led to substantial increases in usage of our resident analytics
platform, suggesting that these features fulfill previously unmet educational needs.

**SSA11-07  Electronic Education Exhibit 'Likes' at the 2014 RSNA Annual Meeting**

*Sunday, Nov. 29 11:45AM - 11:55AM Location: S403A*

**Participants**

Paul M. Bunch, MD, Boston, MA (Presenter) Nothing to Disclose
Jeremy R. Wortman, MD, Boston, MA (Abstract Co-Author) Nothing to Disclose
Katherine P. Andriole, PhD, Dedham, MA (Abstract Co-Author) Nothing to Disclose

**Purpose**

For the second consecutive year, the 2014 RSNA DPS offered electronic education exhibit (EEE) viewers the opportunity to "like" an
EEE. We sought to 1) evaluate any relationship between an EEE's popularity and its chance of winning an award or being selected
for RadioGraphics, 2) evaluate any relationship between an EEE's recognition and its subsequent popularity, and 3) assess overall
audience "like" participation at the 2014 meeting as compared to 2013.

**Method and Materials**

The number of likes each EEE received was recorded from DPS on 1) Wednesday morning before award selections and RadioGraphics
invitations had been announced and 2) Saturday morning after the meeting had concluded. Data analysis was performed by means
of one-way ANOVA.

**Results**

At the 2014 RSNA meeting, there were 1793 EEEs, which received 11074 likes (Mean 6.2, Min 0 [n=124], Max 109 [n=1]). Awards
were given to 404 EEEs (22.5%), which received 3452 likes (31.2%, Mean 8.5, Min 0 [n=13], Max 109 [n=1]). RadioGraphics
invitations were given to 169 EEEs (9.4%), which received 1525 likes (13.8%, Mean 9.0, Min 0 [n=2], Max 54 [n=1]). EEEs receiving awards had significantly more likes prior to award selection (Mean 4.4 vs 3.5, p=0.0035) and at the end of the meeting (Mean 8.5 vs 5.5, p<0.0001) than non-awarded EEEs. EEEs receiving RadioGraphics invitations had significantly more likes prior to invitation announcement (Mean 4.6 vs 3.6, p=0.0272) and at the end of the meeting (Mean 9.0 vs 5.9, p<0.0001) than non-recognized EEEs. Recognized EEEs received significantly more likes over the second half of the meeting than non-recognized EEEs (Mean 4.2 vs 1.9 for awarded vs non-awarded, Mean 4.5 vs 2.2 for invited vs, non-invited, p<0.0001 for both). There was a 152% increase in total EEE likes recorded at the 2014 RSNA meeting as compared to 2013 (11074 vs 4391).

CONCLUSION
The DPS "like" feature at the 2014 RSNA meeting allowed for substantial audience feedback on EEEs, with over 11000 distinct entries made. There was an association between EEE likes and EEE recognition, and EEE recognition was also associated with a subsequent increase in EEE likes. As compared to 2013, EEE viewers at the 2014 meeting recorded 2.5 times more likes.

CLINICAL RELEVANCE/APPLICATION
EEE likes gauge radiologists' opinions of EEEs and may predict awards and RadioGraphics invitations. The DPS like feature was more utilized at the 2014 RSNA meeting as compared to the previous year.

SSA11-08  Structured Reporting of Focal Lesions in the Abdomen to Assess Radiology Trainees' Performance Demonstrates Decreased Detection Errors for Suspicious Lesions with Increased Training
Sunday, Nov. 29 11:55AM - 12:05PM Location: S403A

Participants
Joe C. Wildenberg, MD, PhD, Philadelphia, PA (Presenter) Nothing to Disclose
Po-Hao Chen, MD, MBA, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose
Charles E. Kahn JR, MD, MS, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose
Hanna M. Zafar, MD, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose
Tessa S. Cook, MD, PhD, Philadelphia, PA (Abstract Co-Author) Nothing to Disclose

PURPOSE
Structured reporting (SR) of focal masses in the solid abdominal organs can be used, in the context of education, to assess the ability of radiology trainees to detect and characterize these lesions. Using an existing SR initiative at our institution, we investigated if there was a difference in detection of focal abdominal mass lesions by trainee level.

METHOD AND MATERIALS
All CT and US studies of the abdomen performed between 7/1/2013 and 12/15/2014 in a call setting, without immediate attending input, were reviewed. Trainees evaluated the liver, pancreas, kidneys, and adrenal glands within the SR framework. Numeric codes were analogous to BI-RADS, and corresponded to both the presence of focal masses and the likelihood of malignancy. All preliminary interpretations were subsequently reviewed by attending radiologists, and differences in the numerical categories noted. Non-visualization was representative of a change from an assignment of "no mass" to any benign, indeterminate or suspicious lesion. Data was analyzed by level of training.

RESULTS
Among 12081 studies that met inclusion criteria, residents failed to visualize focal abdominal masses more often than fellows (80/3699, 2.2% versus 128/8382, 1.5%, respectively) (p<0.02). Sub-analysis revealed no difference in detection when the lesion was classified as benign; however, fellows demonstrated a lower miss rate for suspicious lesions (p<0.05). Furthermore, although direct year-to-year comparisons were not significant, there was a near-linear decrease in non-visualization rate with increased trainee year (r=0.96; p<0.05).

CONCLUSION
SR can be leveraged to assess radiology trainees' performance and guide education in call situations. We found that increased training was associated with a lower proportion of missed focal masses. Additionally, we found that inexperienced trainees made more errors when the lesion was eventually classified as suspicious, whereas there was no difference for benign lesions.

CLINICAL RELEVANCE/APPLICATION
Trainee education in the clinical setting is often subjective, with incomplete metrics to assess trainee performance. Structured reporting of focal abdominal masses is an objective metric to understand the progression of trainees' proficiency and provide targeted feedback for studies read in a call setting. The effect of alternative methods of targeted educational outreach to residents on non-visualized abdominal masses can be explored.

Honored Educators
Presenters or authors on this event have been recognized as RSNA Honored Educators for participating in multiple qualifying educational activities. Honored Educators are invested in furthering the profession of radiology by delivering high-quality educational content in their field of study. SSA11-09  TROVE: Open Source Resident Dashboard with Disease Classification Using Natural Language Processing (NLP) and Machine Learning (ML)
Sunday, Nov. 29 12:05PM - 12:15PM Location: S403A

Participants
Kurt T. Teichman, BSc, MEng, New York, NY (Abstract Co-Author) Nothing to Disclose
Shlomo Minkowitz, BA, MD, New York, NY (Presenter) Nothing to Disclose
Charles Hemmann, MS, New York, NY (Abstract Co-Author) Nothing to Disclose
George L. Shih, MD, MS, New York, NY (Abstract Co-Author) Consultant, Image Safely, Inc; Stockholder, Image Safely, Inc;
Consultant, Angular Health, Inc; Stockholder, Angular Health, Inc;

Background
Determining if a radiology resident has met the goals of the residency curriculum, which outlines different pathologies and conditions for imaging, is challenging. Our TROVE dashboard (DEMO: http://demo.trovedashboard.com / SOURCE: http://src.trovedashboard.com) displays the volume of exams and now classifies the radiology reports to determine which diseases a resident has seen during clinical rotations.

Evaluation
Machine learning algorithms are applied using a training dataset from our billing company which provides ICD9 codes for all radiology reports. The disease view of the TROVE dashboard utilizes 174 support vector machine (SVM) classifiers to associate radiology free text reports with 174 specific disease labels, which correspond to diseases that were determined to be important for resident training by the different departmental division chiefs. Resident reports are processed using Natural Language Processing techniques by finding both positive and negative labels for a particular disease and then compiling a MESH concept list of the most common concepts associated with that particular disease to determine features to be used in SVM training. Utilizing solely the impression text of a report, the average F1-score across all 174 svm classifiers is 0.801894 (best = 1.0). Some diseases scored higher such as Carotid Stenosis (0.883001144096) and Wrist Fracture (0.886353355114). Other diseases had lower scores such as Testicular Torsion (0.676691729323). A single report may include multiple diseases and will be classified as such by the SVMs.

Discussion
With an average F1-measure of 0.801894 we can conclude that the methodology outlined above provides fairly robust predictions associated with the SVM classifiers, giving a reasonable estimate of resident experience. Lower scores are generally associated with either improper feature selection and/or shortage of training data which may improve over time with more data. Future work on these SVM classifiers should include the use of MetaMap for better feature selection.

Conclusion
TROVE dashboard, using NLP and ML, provides classification of radiology reports to determine the diseases residents have seen during their clinical rotations.
**Utility of Ungated Free-breathing Through-time Radial GRAPPA in Pediatric Cardiac MRI - Preliminary Results**

**Purpose**
Cardiac MRI (CMR) sequences require ECG gating and multiple breath holds, which may be difficult in children and often require general anesthesia. We sought to compare the image quality and quantitative ventricular parameters with ungated free breathing through-time radial GRAPPA to gold-standard breath-hold cine sequences.

**Method and Materials**
The study included 9 patients, 7 on 1.5 T and 2 on 3 T scanners. Both gold-standard breathhold SSFP scans with ECG gating and free breathing ungated highly under sampled radial bSSFP scans were acquired. Radial data was reconstructed using through-time radial GRAPPA. ESV, EDV, EF and mass were assessed for both scans and compared using two-sided t-tests. Images were evaluated by two independent cardiac imagers for several features including endocardial border detection, blood pool, myocardium, mitral and tricuspid valve, global and regional cardiac wall motion abnormalities on a 5 point scale (1- worst, 5- best). Artifacts were graded on a 5 point scale (1- no artifacts, 5- extensive artifacts).

**Results**
There was excellent correlation of quantitative measurements between the two MRI techniques (EF R=0.89, EDV R=0.99, ESV R=0.93, mass R=0.98). The differences in EF, EDV, ESV and mass between gold-standard and real-time methods were not statistically significant. For the Bland-Altman plot, the mean difference of the measurements between the gold-standard and real-time methods was -0.35% (1.57% and -2.27%) and 95% limits of agreement contained 100% of the difference scores. On qualitative assessment, mitral valve was seen well (p=0.01) in SSFP but all the other features were comparable in both sequences. The mean artifact score was significantly lower in the real- time images (1.1 vs 2.8, p < 0.005). The mean scan time was also shorter with real time real time method (4.1 mins vs 6.5 mins, p < 0.001)

**Conclusion**
Real-time functional CMR with through-time radial GRAPPA performed without ECG-gating under free-breathing can be considered as an alternative to gold-standard breath hold cine imaging for the evaluation of quantitative and qualitative parameters in pediatric patients with comparable results, fewer artifacts and shorter scan times.

**Clinical Relevance/Application**
This novel sequence is useful in cardiac MRI of children, who often are not compliant with breath holding instructions and may thus obviate the need for general anesthesia in these children.

Joseph Y. Cheng, PhD, Stanford, CA (Abstract Co-Author) Nothing to Disclose
Maria M. Lamacie, MD, Toronto, ON (Abstract Co-Author) Nothing to Disclose

METHOD AND MATERIALS

With IRB approval, informed consent, and HIPAA compliance, 22 consecutive patients with suspected or known congenital heart disease (10 males, 6.4±4.8 years) referred for 3T ferumoxytol-enhanced cardiac MRI were prospectively recruited. Complete ventricular coverage was obtained with both axial 4D flow and standard two-dimensional short-axis multi-slice SSFP sequences. Two blinded cardiovascular imagers independently segmented the images for LV myocardium on end systolic (ES) and end diastolic (ED) images, thus yielding four blinded measurements of LV mass by each imager in each subject. Linear regression, ANOVA, Bland-Altman analysis, and intra-class correlation (ICC) were used to assess the hypothesis that the accuracy, precision and inter-observer variability of LV mass measurements are not significantly different between 4D flow and cine SSFP acquisitions.

RESULTS

Significant positive correlations were found for LV mass between 4D flow and SSFP at ED (32.8±14.2g vs. 33.3±14.4g, r=0.989, p<0.001) and ES (33.2±14.4g vs. 31.8±13.6g, r=0.988, p<0.001). Mean bias between ED and ES LV mass measurements as a percentage of the mean were -2.1±10.3% for 4D flow and 4.2±4.7% for SSFP, respectively. There was no significant difference between 4D flow and SSFP with respect to mean square difference of ED-ES LV mass (F=2.05, p=0.159). High levels of inter-observer agreement were achieved for LV mass with 4D flow (ED ICC 0.948 (95%CI 0.880, 0.978); ES ICC 0.936 (95%CI 0.851, 0.973)) and SSFP (ED ICC 0.960 (95%CI 0.906, 0.983); ES ICC 0.953 (95%CI 0.890, 0.980)), with overlapping confidence intervals.

CONCLUSION

Ferumoxytol-enhanced 4D flow MRI determines LV mass with comparable precision, accuracy and inter-observer agreement relative to cine SSFP.

CLINICAL RELEVANCE/APPLICATION

4D flow imaging allows for accurate and reliable assessment of LV mass, potentially reducing costs and increasing patient comfort due to shortened data acquisition times.

SSA03-03  

Deformable Registration Based Analysis of Cine MR for Quantification of Regional Myocardial Function: Comparison to MR Feature Tracking and Speckle-Tracking Echocardiography

Sunday, Nov. 29 11:05AM - 11:15AM Location: S504AB

Purpose

The aim of this study is to assess deformable registration algorithms using cine SSFP data for analysis of myocardial strain in comparison to cine SSFP feature tracking (FT) and speckle-tracking echocardiography (STE).

METHOD AND MATERIALS

In this prospective study, 28 patients with thalassemia major and 10 healthy volunteers underwent cardiac MRI at 1.5T (Avanto fit, Siemens, Germany). LV peak systolic global longitudinal (GLS) based on 3 long axis SSFP cine images was measured using MR feature tracking (2D Cardiac Performance Analysis MR, Tomtec, Germany) and a prototype automatic contouring tool with integrated inverse deformable registration analysis (DRA) (TrufiStrain, Siemens CT, Princeton, US) based on material coordinates assessment (Lagrangian strain). Repeated analysis was performed for both MR approaches to assess for measurement variability. 2D speckle-tracking echocardiography (STE) (EchoPAC, GE, UK) was performed within 2h of the MR examination.

RESULTS

STE based longitudinal strain analysis was feasible in 89% of subjects while both MR approaches successfully analyzed all data sets,
Purpose

Prior echocardiographic studies of congenital bicuspid aortic valve (BAV) have found evidence of subclinical systolic and diastolic dysfunction. Patients with BAV commonly undergo cardiac magnetic resonance imaging (CMR) for evaluation of valvular function and aortic dimensions. Feature tracking CMR (FT-CMR) is a technique that allows for assessment of myocardial strain using standard 2D cine sequences. The purpose of this study was to investigate differences in myocardial strain between BAV patients with preserved ejection fraction and healthy controls using FT-CMR.

Method and Materials

Patients with isolated BAV and normal ejection fraction (EF), who had previously undergone CMR (n=36), were compared to an age- and sex-matched sample of healthy control subjects (n=10). FT-CMR strain analysis software (Circle Cardiovascular Imaging, Inc.) was used to measure LV mass, EF and 2D ventricular strain parameters. Comparison of means was performed with student’s t-test assuming unequal variance.

Results

Average age was 30.4 ± 10.7 for the BAV group and 29.4 ± 8.7 for healthy controls (p=0.8). Gender distribution was similar between groups (BAV: 47% F, Control: 50% F). The majority of BAV patients had mild or no valve dysfunction by echocardiography (stenosis: 64%, insufficiency: 72%). There was a trend towards higher global peak circumferential and radial strain in BAV patients compared to controls ([−19.8 ± 1.8 vs. −18.8 ± 1.2%, p=0.07] and [40.3± 6.4% vs. 36.8 ± 4.3%, p=0.08] respectively), but these differences did not reach statistical significance. Compared to controls, myocardial mass index was higher in BAV patients (61.3 ± 13.5 vs. 46.1 ± 8.7 g/m², p<0.001). Peak diastolic circumferential and radial strain rates were lower in BAV patients compared to controls ([0.83 ± 0.21 vs. 1.1 ± 0.21 s⁻¹, p=0.01] and [2.0 ± 0.66 vs. 2.8 ± 0.50 s⁻¹, p=0.02] respectively). Longitudinal strain and strain rate were not different between groups.

Conclusion

Feature-tracking CMR can identify abnormalities of left ventricular strain in a clinical cohort of BAV patients with normal EF. Differences in diastolic strain rate between BAV and control groups may indicate evidence of early diastolic dysfunction.

Clinical Relevance/Application

Feature tracking cardiac MRI reveals abnormalities in ventricular function in patients with bicuspid aortic valve and normal ejection fraction.
METHOD AND MATERIALS

94 CMR and 99 GBPS were measured by two physicians. GBPS was performed using 2 automatic algorithms: BP-SPECT and QBS and a semi-automatic algorithm: TOMPOOL. Relative Inter-Observer Variability (IOV) was defined as the absolute difference between the two calculated measurements normalized to their average and expressed as a percentage.

RESULTS

The overall IOV (%) was greater using semi-automatic GBPS procedure (TOMPOOL: 16±20%) than CMR (12±14%) or automatic GBPS algorithm (QBS: 8±12%, BP-SPECT: 6±6%). The IOV of CMR challenged GBPS in 2 subgroups of heart disease treated arrhythmia (6±5%) and hyperdynamic cardiomyopathy / cirrhosis (4±3%). Overall, the factors that most influenced the IOV were right valve regurgitation (20±18%; n=27), dilated cardiomyopathy (20±20%; n=24), RVEF<45% (20±18%; n=32), end-systolic diameter of the left ventricle>41mm (17±19%; n=30) and left valve regurgitation (17±20%; n=27).

CONCLUSION

The most reproducible procedure is automatic GBPS. Changes occurring during the follow-up should be interpreted cautiously on CMR (IOV: 12%) or semi-automatic GBPS (IOV: 16%). The parameters responsible for increased IOV on CMR are: valve regurgitation, altered ejection fraction and enlargement of the left ventricle. The reproducibility of CMR challenged GBPS in treated arrhythmia and hyperdynamic heart disease.

CLINICAL RELEVANCE/APPLICATION

The estimation of RVEF is crucial in a wide range of heart disease. A reproducible technique is necessary for an optimal follow-up of RV dysfunction.

SSA03-06  Left Ventricular Function Can Be Adequately Assessed Using Compressed Sensing Cine Imaging with High Spatial and Temporal Resolution

Sunday, Nov. 29 11:35AM - 11:45AM Location: S504AB

PURPOSE

Cardiac magnetic resonance cine imaging currently bases on time consuming cine SSFP sequences with limited spatial and temporal resolution. Here we assessed whether two compressed sensing cine sequences with high spatial or high temporal resolution can reliably quantify left ventricular volumes and mass.

RESULTS

Small differences were observed between standard SSFP and sparse 1 for end-diastolic volume (EDV, median difference 4ml, p=0.044), stroke volume (SV, mean difference, 7±10ml, p=0.013), ejection fraction (EF, 1%, p=0.029), and myocardial mass (8±7g, p=0.001), but no significant difference was found for end-systolic volume (ESV, p=0.135). No significant differences were observed between standard SSFP and sparse 2 regarding EDV (-1±5ml, p=0.528), ESV (-3±5ml, p=0.058), SV (2±5ml, p=0.139), and EF (1±3%, p=0.105), except for myocardial mass (-6±8g, p=0.017). Intraclass correlation coefficients comparing standard SSFP with both sparse sequences were at least 0.95. Bland-Altman analysis and Passing-Bablok regression showed good agreement between all sequences. Intraobserver agreement was good to excellent (kappa: 0.76-0.90).

CONCLUSION

Compressed sensing cine sequences with improved spatial or temporal resolution enable reliable assessment of LV volumes and mass.

CLINICAL RELEVANCE/APPLICATION

Compressed sensing cine imaging allows an adequate assessment of the left ventricular function and an improved spatial and temporal resolution.

SSA03-07 CMR-derived TAPSE Is a Useful Marker for Detection of RV Function Changes in Patients with Chronic Thromboembolic Pulmonary Hypertension

Sunday, Nov. 29 11:45AM - 11:55AM Location: S504AB

Participants

Xiaojuan Guo, PhD, Beijing, China (Presenter) Nothing to Disclose
Min Liu, Beijing, China (Abstract Co-Author) Nothing to Disclose
Zhanhong Ma, Beijing, China (Abstract Co-Author) Nothing to Disclose
Tao Jiang, Bei Jing, China (Abstract Co-Author) Nothing to Disclose
Shuang Wang, MD, Beijing, China (Abstract Co-Author) Nothing to Disclose
Tianjing Zhang, Beijing, China (Abstract Co-Author) Employee, Siemens AG

PURPOSE

The aim of this study is to determine whether CMR-derived right ventricular fractional shortening (RVFS), tricuspid annular plane systolic excursion with a reference point within the right ventricular apex (TAPSEin) and with one outside the ventricle (TAPSEout): (1) can predict pulmonary hypertension, (2) correlates with pulmonary vascular resistance index (PVR) and main pulmonary artery
flow in patients with CTEPH.

METHOD AND MATERIALS

37 patients (age, 50.1 ± 11.7 years; male, 22) with chronic thromboembolic pulmonary hypertension (CTEPH) and 15 healthy subjects (age, 47.4 ± 13.6 years; male, 9) underwent CMR imaging at 3T. The four-chamber Cine images were acquired to get the distance between the cutting edge of the tricuspid annulus with the RV free wall and the RV apex or a reference point outside the RV apex in end-diastole (end-diastolic length (EDL) in or EDLout) and end-systole (end systolic length (ESL) in or ESLout). All patients underwent right heart catheterization to get PVR. The parameters between different group were compared by an independent t-test. The ROC curve analysis was used to evaluate the diagnosis value of TAPSE derived by CMRI. TAPSE obtained by CMRI were correlated with PVR and MPA mean velocity by Spearman or Pearson correlation analysis.

RESULTS

TAPSEout (t=5.69, p<0.001), TAPSEin (t=5.83, p<0.001) and RVFS (t=6.05, p<0.001) revealed a significant difference between patients with CTEPH and the healthy group. ROC curve analysis showed that TAPSEout had a high predictive value for CTEPH (Auc=0.92 for TAPSEout, 0.89 for TAPSEin, 0.88 for RVFS, p<0.01). The diagnostic threshold for TAPSEout was 15.7 mm for CTEPH patients. In patients with CTEPH, PVR showed a significant but weak correlation with TAPSEout (r=0.31, p=0.04) and no correlation with TAPSEin (r=-0.09, p=0.61) and RVFS (r=-0.08, p=0.64). There was a moderate correlation between MPA mean velocity and TAPSEout (r=-0.54, p<0.03) and no correlation with TAPSEin (r=-0.13, p=0.62) and RVFS (r=0.06, p=0.83).

CONCLUSION

CMR-derived TAPSEout is a useful marker to predict CTEPH. TAPSEout shows a good correlation with PVR and MPA mean velocity in CTEPH patients. TAPSEout might be a potential indicator for detection of RV function changes.

CLINICAL RELEVANCE/APPLICATION

CMR - determined TAPSE measurement is a quick screening method to identify patients with potential RV dysfunction and to select patients in whom a more detailed analysis would be used.

SSA03-08 Body Mass Index-Based Reduction of Radiation Exposure in Coronary CT Angiography Using a 3rd Generation Dual-Source CT Scanner

PURPOSE

To retrospectively investigate the potential of further dose reduction at coronary computed tomography angiography (CCTA) based on body mass index (BMI) using a 3rd generation dual-source CT (DSCT) scanner and automated tube voltage selection.

METHOD AND MATERIALS

We evaluated 231 patients who underwent CCTA with a 3rd-generation DSCT. Prospectively ECG-triggered adaptive sequential acquisition at 70, 80, 90, 100 and 120kV (pulsing window 30-90%, full dose at 70% of the cardiac cycle) was performed with automated attenuation-based selection of tube current and voltage and advanced modeled iterative reconstruction. Patients were divided in three classes: 1, 70-80kV (n=44); 2, 90-100kV (n=59) and 3, 120kV (n=118). BMI and effective dose (ED) was recorded. Vascular attenuation in proximal and distal coronary arteries was measured. Contrast-to-noise ratio (CNR) was calculated. To subjectively evaluate vessel enhancement and image noise five-point scales were used.

RESULTS

Image quality was diagnostic in 98.7% of the examinations. BMI between the groups was significantly different with 24.2 kg/m2 in group 1, 27.5 kg/m2 in group 2 and 34.3 kg/m2 in group 3 (p<0.0006 and p<0.0001, respectively). Proximal and distal CNR was significantly lower in group 1 compared to group 2 (14.5vs12.8 and 11.4 vs 10.4, p=0.049 and 0.007) and in group 3 compared to group 2 (13.6 and 10.9; p=0.002 and 0.001). However, no significant differences between the groups were shown by subjective image quality analysis (p>0.05). Intragroup comparison in group 1 and 2 revealed no significant differences regarding the BMI and objective image quality parameters between 70 and 80kV (mean BMI: 24.0±3.0 vs 25.1±4.0 kg/m2, p=0.370; mean proximal CNR: 15.0vs14.1, p=0.492) and between 90 and 100kV (mean BMI: 27.7±4.6 vs 27.2±4.3 kg/m2, p=0.717; mean proximal CNR: 16.1vs17.5, p=0.429). However, ED was significantly lower for 70kV in comparison to 80kV (1.7±1.4vs2.7±1.5 mSv, p=0.001) as well as for 90kV compared to 100kV (5.0±4.3 vs 6.5±3.3 mSv, p=0.011). Mean ED at 120kV was 11.2±4.4 mSv.

CONCLUSION

For CCTA with 3rd generation DSCT automated tube voltage selection is effective in reducing the ED according to patient size.

CLINICAL RELEVANCE/APPLICATION

Automated tube voltage selection can be used to achieve significant reduction of radiation dose in CCTA in patients with a wide range of body types.

SSA03-09 The Impact of Dipper Status in Hypertension on Cardiac Structure, Global Function and Regional Myocardial Strain: Insights from Cardiac Magnetic Resonance (CMR)
PURPOSE

The loss of normal nocturnal dip in blood pressure in hypertension has adverse prognostic implications. We investigated the impact of dipper status on cardiac structure and function using cardiac magnetic resonance (CMR).

METHOD AND MATERIALS

24 hour ambulatory blood pressure monitoring (ABPM) and comprehensive CMR including late gadolinium enhancement (LGE) for myocardial scar assessment (1.5T Avanto, Siemens) were performed in 72 hypertensive patients referred from our tertiary hypertension clinic. Dipper status (n=33) was defined as >10% drop and non-dipper (n=39) as 0-10% drop in nocturnal systolic BP (SBP) versus diurnal SBP. Left ventricular mass (LVM) and volumes indexed to body surface area. Regional myocardial strain was estimated from the global mid LV from a 3D model generated from 4-chamber, 2-chamber and short axis cines (cvi42, Circle Cardiovascular Solutions Inc.). Fishers exact or unpaired student T tests were used as appropriate.

RESULTS

The results are show in Table 1. Non-dippers were significantly older than dippers (54±14 vs 46±15 years p<0.05). There was no difference in overall SBP and DBP between dippers and non-dippers but the latter had significantly higher nocturnal SBP (152±23 vs 129±13 mmHg p<0.0001) and DBP (82±14 vs 76±12 mmHg p<0.05). There were non-significant trends towards higher indexed LVM (90±25 vs 84±18g/m2) and prevalence of subendocardial LGE suggesting previous subclinical myocardial infarction (11% vs 3%) in non-dippers compared to dippers. Time to peak longitudinal strain was significantly higher in non-dippers compared to dippers (346±68 vs 316±54ms p<0.05) despite no significant difference in BP. A similar trend was observed for time to peak radial strain (332±68 vs 306±68ms p=0.07).

CONCLUSION

Significantly higher nocturnal SBP and DBP occur in non-dippers versus dippers. Trends towards higher indexed LVM, prevalence of subendocardial MI and prolonged time to peak strain. The latter suggests increased peripheral vascular resistance in non-dippers. These findings may help explain the adverse cardiovascular risk conferred by non-dipper status.

CLINICAL RELEVANCE/APPLICATION

CMR provides insights into different structural and function differences in non-dippers versus dippers and has potential to aid risk stratification in patients with hypertension.
Nuclear Medicine Keynote Speaker: Targeting PSMA for Imaging Cancer

Sunday, Nov. 29 10:45AM - 11:05AM Location: S505AB

Next Generation Digital PET/CT: A Phase I Intra-Individual Comparison with Current Photomultiplier TOF PET/CT

Sunday, Nov. 29 11:05AM - 11:15AM Location: S505AB

Staging of Patients with Advanced Melanoma - CT or PET/CT? Impact of Imaging on Decision Making and Survival Analysis of Patients with Stage III and IV Melanoma

Sunday, Nov. 29 11:15AM - 11:25AM Location: S505AB

PURPOSE
To objectively assess the oncologic imaging characteristics of a next generation solid state digital PET detector system compared to current state of the art photomultiplier based time of flight PET/CT imaging.

METHOD AND MATERIALS
A next generation, solid state, digital PET/CT system (Vereos 64 TF, Philips Healthcare) operated in pre-factory release was used to compare image characteristics in 25 clinical care patients to current photomultiplier detector based time of flight PET/CT. The order of imaging (placement on the system) was randomized with the SOC imaging at 75 min and investigational at 55 and 95 min p.i. Image characteristics were assessed by blinded readers (3) using a scoring system and blinded quantitative ROI analysis

RESULTS
All matched exams were rated evaluable with decay corrected higher count intensity on all digital PET images. Image quality and detection ability was consistently rated significantly higher (p<.01) on the digital PET images. Comparing different reconstruction approaches, 2mm whole body, PSF with Gaussian filtering achieved the highest image quality score. Confidence of lesion detectability was rated significantly higher on the digital PET when evaluating lesions of <15 mm. While larger lesions and soft tissue presented equivalent SUV readouts at ROI analysis, smaller (<15 mm) and metabolic active lesions revealed substantially higher SUV values suggestive that also in vivo the improved recovery coefficient will lead to more correct, precise metabolic activity readouts. Tracer dose simulations indicate that no impact on quality and detectability was found while reducing the count equivalency from 13 mCi FDG to 6mCi.

CONCLUSION
The digital PET system demonstrated higher count sensitivity, improved spatial and contrast resolution that led to better lesion detection and improved quantification especially of small, metabolic active lesions. This Phase I trial suggests, that the next generation PET detection technology has the opportunity to substantially advance the visual and quantitative quality, accuracy and measurement reproducibility for clinical PET imaging. Furthermore, substantially reduced tracer dose appear feasible in clinical PET.

CLINICAL RELEVANCE/APPLICATION
This presentation introduces the clinical capabilities of the next generation digital detector PET/CT technology for oncologic PET imaging and present initial clinical findings on improved lesion visualization, detection and quantification.
Comparison of Pulmonary Nodule Detection in Lung Cancer Patients Using Whole Body FDG PET/CT, High Resolution Lung Reformat of FDG PET/CT, or Diagnostic Breath Hold Chest CT

Sunday, Nov. 29 11:25AM - 11:35AM Location: SS05AB

David M. Naegger, MD, San Francisco, CA (Abstract Co-Author) Nothing to Disclose

PURPOSE

Previous reports have documented that pulmonary nodules can be missed on the non-breath hold CT portion of FDG PET/CTs. We evaluated the image quality and rate of pulmonary nodule detection of whole body PET/CT (WB PET/CT), high-resolution sharp lung reconstruction of PET/CT (HR PET/CT), and diagnostic breath hold chest CT (BH CT).

METHOD AND MATERIALS

A cohort of 25 patients was identified who had a history of lung cancer as well as a PET/CT staging or restaging scan and a diagnostic chest CT within 15 days of each other. Per our standard protocol, all PET/CTs included a high resolution lung reformat with sharp reconstruction filter and 2 mm slice thickness. WB PET/CT, HR PET/CT, and BH CT were reviewed by 3 radiologists, and the number and size of pulmonary nodules detected were recorded, as was a subjective assessment of image quality. Statistical significance of differences between reader and modality groups was analyzed by two-way repeated measures ANOVA.

RESULTS

On average, 2.84 nodules were found per patient with WB PET/CT, 3.93 nodules with HR PET/CT, and 3.91 nodules with BH CT. When only nodules less than or equal to 8 mm in size were considered, BH CT (2.86) and HR PET/CT (2.95) revealed more nodules per patient than WB PET/CT (1.99). While statistically significantly more nodules and nodules less than 8 mm were detected by HR PET/CT and BH CT than WB PET/CT (p<0.001) no difference was noted between the two higher resolution modalities. Comparisons of image quality revealed reader preference for BH CT over HR PET/CT (p = 0.01), and HR PET/CT over WB PET/CT (p<0.001).

CONCLUSION

More pulmonary nodules are detected using HR PET/CT reformats than the standard WB PET/CT images, and overall image quality was rated as higher. The ability to detect nodules was indistinguishable from dedicated BH CTs. These data suggest that use of high-resolution reformats of PET/CT images of the lungs increases sensitivity for pulmonary nodule detection, approving that of dedicated chest CT.
Routine application of a high-resolution lung reformat to PET/CT images may increase the rate of pulmonary nodule detection to rates comparable to routine chest CT.

SSA15-06  Value of FDG PET/CT for Systemic Staging of Newly Diagnosed Invasive Lobular Breast Cancer (ILC) as Compared with Invasive Ductal Breast Cancer (IDC)

Sunday, Nov. 29 11:35AM - 11:45AM Location: S505AB

PURPOSE
While NCCN guidelines consider FDG PET/CT for systemic staging of newly diagnosed stage III breast cancer patients, factors in addition to stage may influence PET/CT utility. For example, primary ILC demonstrates lower conspicuity on FDG PET than the more common IDC. We evaluated utility of PET/CT systemic staging of newly diagnosed patients with ILC as compared to IDC.

METHOD AND MATERIALS
A retrospective study was performed under IRB waiver. Our Hospital Information System was screened for ILC patients who underwent PET/CT 2006-2013 prior to systemic or radiation therapy. Initial stage was determined from records of physical exam, mammography, ultrasound, MRI and/or surgery. PET/CT was evaluated to identify unsuspected distant metastases. A cohort of patients with stage III ILC was evaluated for comparison. Upstaging rates were compared using chi square test and the relative risk with 95% CI was calculated.

RESULTS
146 ILC patients fulfilled inclusion criteria. PET/CT revealed unsuspected distant metastases in 12 patients (8%): 0 of 8 initial stage I, 2 of 50 (4%) stage II, and 10 of 88 (11%) stage III. All patients upstaged to IV were confirmed by pathology. 3 of the 12 upstaged patients were upstaged only by the CT component of the PET/CT, as metastases were non-FDG-avid. In the comparison stage III IDC cohort, 22% (20 of 89) of patients were upstaged to IV by PET/CT. All 20 demonstrated FDG avid metastases. The relative risk of PET/CT revealing unsuspected distant metastases in stage III IDC patients was 1.98 times (95% CI 1.26-3.98) that of stage III ILC patients (p=.007).

CONCLUSION
FDG PET/CT is more likely to reveal unsuspected distant metastases in stage III IDC patients than in stage III ILC patients. In addition, some ILC patients were upstaged only by the CT component of PET/CT, as the metastases detected on CT were not FDG-avid. As PET/CT may have lower impact on systemic staging of ILC patients, ILC patients should not be pooled with IDC patients when exploring the utility of PET/CT.

CLINICAL RELEVANCE/APPLICATION
NCCN guidelines and planned studies may need to consider histologic subtype of breast cancer. FDG PET/CT may have less impact on systemic staging of newly diagnosed ILC than IDC.

SSA15-07  FDG PET/CT and Recurrent Colorectal Cancer Patient Survival: FDG Avidity and Tumor Burden

Sunday, Nov. 29 11:45AM - 11:55AM Location: S505AB

Participants
Wael M. Marashdeh, MBBS, MD, Baltimore, MD (Presenter) Nothing to Disclose
Charles Marcus, MD, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Mehti Taghipour, MD, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Se Jin Ahn, MD, Baltimore, MD (Abstract Co-Author) Nothing to Disclose
Rathan M. Subramaniam, MD, PhD, Baltimore, MD (Abstract Co-Author) Travel support, Koninklijke Philips NV

PURPOSE
The aim of the study was to assess the value of quantitative PET parameters in the prediction of survival in recurrent colorectal cancer patients.

METHOD AND MATERIALS
This was a retrospective study of 126 patients with biopsy proven colorectal cancer recurrence from 2000 to 2012. Maximum and peak standardized uptake values (SUVmax, SUVpeak), metabolic tumor volume (MTV) and total lesion glycolysis (TLG) were measured for each biopsy confirmed recurrent lesion using gradient segmentation method. The median follow up period was 32.1 months. The primary outcome was overall survival (OS). Kaplan-Meier survival plots and Cox regression analyses were performed.

RESULTS
The mean ± SD SUVmax, SUVpeak, total TLG and total MTV of the study population were 7.1 ± 4.3, 5.3 ± 3.2, 378.3 ± 917.1g and 234.2 ± 420.8mL, respectively. Multivariate cox regression analysis showed total TLG (p=0.001) and total MTV (p=0.001) were associated with OS. Kaplan-Meier survival analysis was performed and SUVmax (threshold=5.9, HR=2.5; 95%CI:1.4-4.2; p=0.0001), SUVpeak (threshold=4.31, HR=2.1; 95%CI:1.2-3.5; p=0.005), total TLG (threshold=137.1g, HR=2.9; 95%CI:1.7-4.8; p<0.0001) and total MTV(threshold=32.17mL, HR=2.5; 95%CI:1.5-4.2; p<0.0001) were significant predictors of survival during follow-up. An
integrated risk stratification model using SUVmax and total MTV to stratify patients into three subgroups predicted patient survival outcomes (HR=2.1, 95% CI:1.5-2.9; log-rank p<0.0001).

**CONCLUSION**

FDG PET SUVmax, SUVpeak, TLGtotal, MTVtotal and an integrated risk stratification with FDG avidity and tumor burden provide significant prognostic information in patients with biopsy proven recurrent colorectal cancer.

**CLINICAL RELEVANCE/APPLICATION**

FDG PET/CT in recurrent colorectal cancer can help stratify patients in different groups for which different treatment strategies can be applied.

**SSA15-09**  
**Association between Prognosis and FDG-PET Parameters, ADC of MRI and Oncogene Expression in Pancreas Cancer**

Sunday, Nov. 29 11:55AM - 12:05PM Location: S505AB

Kazuhiro Kondo, Miyazaki, Japan (Abstract Co-Author) Nothing to Disclose  
Toshinori Hira, MD, PhD, Miyazaki, Japan (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

The study was done to determine the significant prognostic factor among FDG-PET parameters, apparent diffusion coefficients (ADC) of MRI and various oncogenes expression in pancreas cancer.

**METHOD AND MATERIALS**

Sixty-five pancreas invasive ductal cancer patients those underwent F-18 FDG PET/CT and subsequent surgical resection were evaluated. The maximum standardized uptake value (SUVmax), the peak of standardized uptake value (SUVpeak), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) were calculated on 18F-FDG PET/CT in both early (1hr) and delayed (2hr) examinations. The threshold value for calculating MTV was 40% of SUVmax. In addition, apparent diffusion coefficient (ADCmean and ADCmin) of MRI, various oncogenes expressions including EGFR, VEGFA, Ki-67, HIF-1, KRAS, BRAF, CDH13 were evaluated. Among various clinical parameters including imaging parameters, independent significant prognostic factors for overall survival (OS) were determined by multivariate analysis with Cox proportional hazards model. Among various significant prognostic parameters, univariate analysis with mantel-cox test was done for comparing OS.

**RESULTS**

The pathologic T (pt) stage, TLG on early PET image, SUV max on delayed images and ADCmean was significant prognostic factor for OS (<0.05). Regarding gene expressions, only KRAS was significant predictive factors (P <0.05). In univariate analysis, patients of larger TLG (>=55) showed higher cumulative survival rate compared with that of smaller TLG group (<55). Similarly, lower ADCmean (<1300) showed shorter OS than that of higher ADCmean (>=1300).

**CONCLUSION**

Both FDG parameters (TLG on early PET image, SUV max on delayed images) and ADCmean were significant parameters for predicting OS, in addition to pt stage and KRAS expression. Thus, both 18F-FDG PET/CT and MRI diffusion images can provide useful prognostic information for patients undergoing resection of pancreatic cancer.

**CLINICAL RELEVANCE/APPLICATION**

In the prediction of prognosis of invasive ductal pancreas cancer after surgical operation, TLG of FDG-PET and ADCmean of MRI were useful imaging parameters.

**SSA15-09**  
**Body Weight-based Protocols during Whole Body FDG PET/CT Significantly Reduces Radiation Dose without Compromising Image Quality**

Sunday, Nov. 29 12:05PM - 12:15PM Location: S505AB

Participants
Charbel Saade, MS, Beirut, Lebanon (Presenter) Nothing to Disclose  
Mohamed B. Haidar, MD, Beirut, Lebanon (Abstract Co-Author) Nothing to Disclose  
Ahmad Ammous, Beirut, Lebanon (Abstract Co-Author) Nothing to Disclose  
Mukbil H. Hourani, MD, Beirut, Lebanon (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To investigate radiation dose reduction during head to mid thigh fluorodeoxyglucose (FDG) positron emission tomographic (PET)/computed tomography by employing weight based protocols.

**METHOD AND MATERIALS**

520 consecutive patients were referred for FDG PET/CT study using a 16-detector PET/CT. Patients were allocated to one of two scanning protocols: Group A, the conventional protocol; 120 kVp, 120 mAs, 0.5 sec rotation time, pitch 0.8mm/rot across all body weights; Group B, employed a 4 tier body weight protocol: protocol A: ≤ 60 kg: 140 kVp, 35 mAs, 0.75 sec rotation time, pitch 0.8mm/rot; group B: 60 - 80 kg: 140 kVp, 50 mAs, 0.75 sec rotation time, pitch 0.8mm/rot; group C: 80 - 100 kg: 140 kVp, 65 mAs, 0.75 sec rotation time, pitch 0.8mm/rot; group D: > 100 kg: 140 kVp, 100 mAs, 0.75 sec rotation time, pitch 0.8mm/rot all protocols employed tube current modulation. Patient demographics were measured. Age and sex-specific lifetime attributable risk (LAR) of individual cancers were estimated using the approach of BEIR VII and summed to obtain whole body LAR.
RESULTS

Mean patient demographics demonstrated no significant difference. Mean effective dose CTDIvol and DLP significantly reduced in protocol B (CTDIvol: 4.60 ± 1.49, DLP: 823.35 ± 280.70 mSv) compared to A (CTDIvol: 7.36 ± 1.79, DLP: 1260.96 ± 304.7 mSv) (p<0.0001). Mean FDG administration demonstrated no significant differences in each protocol (p=0.873). Contrast to noise ratio demonstrated no differences between each group (p<0.21). Mean LAR cancer risk was significantly reduced for females by 35% and males 125% in protocol B compared to A (p<0.04).

CONCLUSION

Significant reduction in radiation dose can be achieved using patient-specific body weight based protocols during whole-body FDG PET/CT without compromising image quality.

CLINICAL RELEVANCE/APPLICATION

FDG and PET/CT have revolutionized the practice of medicine. With the expanding use of PET/CT, ionizing radiation may eventually result in an increased incidence of cancer in the exposed population. This problem can be minimized by optimizing the CT protocol to achieve optimal image quality with the lowest possible radiation dose

Sub-Events
VSPD11-01 Malformations of Cortical Development

Participants
Robert C. McKinstry III, MD, PhD, Saint Louis, MO, (mckinstryb@mir.wustl.edu) (Presenter) Travel support, Siemens AG Speaker, Siemens AG

LEARNING OBJECTIVES
A radiologist attending this session will learn 1) The stages of cortical development. 2) The malformations associated with abnormal neuronal proliferation and/or apoptosis. 3) The malformations associated with abnormal neuronal migration. 4) Learn the malformations associated with abnormal postmigrational development

ABSTRACT
This presentation will review the stages of normal cerebral cortical development. Malformations of cortical development will be organized according to abnormal development at each stage: proliferation/apoptosis, migration, and postmigrational organization. Tubulopathies (e.g., polymicrogyria) and defects in the mTOR pathway (e.g., Tuberous Sclerosis) will illustrate emerging knowledge tying genotype to endophenotype.

VSPD11-02 Comparison of Three Diffusion Models for Differentiating Low- and High-Grade Pediatric Brain Tumors

PURPOSE
To evaluate the performance of monoexponential, biexponential, and continuous time random walk (CTRW) diffusion models for differentiating low-grade (LG) and high-grade (HG) pediatric brain tumors.

METHOD AND MATERIALS
With IRB approval, 54 children (4 months to 13 years old) with brain tumors were enrolled in the study and underwent MRI scans at 3T. The imaging protocol included pre-/post-contrast T1, T2, FLAIR, and diffusion-weighted imaging with 12 b-values (0 to 4000 s/mm²). The parameters of the mono-exponential (apparent diffusion coefficient, D), biexponential (fast and slow diffusion coefficients, Df and Ds; fast diffusion fraction, f) and CTRW (diffusion coefficient, Dm; fractional powers of the waiting time and jump length, α and β) models were estimated from the diffusion data. Surgical biopsy or surgery was performed to determine the tumor grade histopathologically according to the WHO guidelines, resulting in 24 patients with LG and 30 with HG tumors. The mean values of all parameters over the tumor ROIs were compared between the two groups using a Mann-Whitney-Wilcoxon U-test. A k-means clustering algorithm was employed to differentiate LG and HG tumors based on the biexponential or CTRW parameters, followed by a comparison using histopathology as a reference.

RESULTS
Significant differences between the two tumor groups (LG vs. HG) were observed in the parameters of any of the three models with p-values < 0.001 (D : 0.90±0.34 vs. 0.56±0.17 in monoexponential; Df : 2.6±1.1 vs. 1.8±0.5, Ds : 0.58±0.1 vs. 0.31±0.1, f : 0.73±0.11 vs. 0.59±0.09 in biexponential; Dm : 1.5±0.5 vs. 0.75±0.2, α : 0.95±0.04 vs. 0.90±0.03, β : 0.92±0.07 vs. 0.81±0.06 in CTRW, with D’s in units of µm²/ms). The combination of CTRW parameters produced better accuracy (85% vs. 79%), sensitivity (87% vs. 83%), and specificity (83% vs. 75%) than the combination of biexponential parameters for identifying tumor grades. Both models outperformed the monoexponential model in accuracy (75%) and specificity (54%).

CONCLUSION
The CTRW diffusion model performed the best in determining pediatric brain tumor malignancy when compared with the monoexponential and biexponential models.

CLINICAL RELEVANCE/APPLICATION
The CTRW diffusion model can provide quantitative imaging markers to improve diagnosis of pediatric brain tumors.
Intravoxel incoherent motion (IVIM) is a non-invasive MR imaging technique to measure microcirculation and diffusivity simultaneously. The purpose of this study was to evaluate the utility of perfusion fraction (f) and diffusion coefficient (D) derived from IVIM to characterize pediatric intracranial tumors.

METHOD AND MATERIALS
This retrospective study included 16 children (M: F = 9: 7; age range 2 month-19 year-old, median 5 year). There were 6 high-grade tumors (HGTs; 3 anaplastic ependymoma, 1 glioblastoma, 1 medulloblastoma, and 1 atypical teratoid/rhabdoid tumor), 9 low-grade tumors (LGs; 4 pilocytic astrocytoma, 2 craniopharyngioma, 1 diffuse astrocytoma, 1 choroid plexus papilloma, and 1 subependymoma) and 1 germinoma. IVIM imaging was obtained using single-shot SE-EPI sequence with 13 b-factors (0, 10, 20, 30, 50, 80, 100, 200, 300, 400, 600, 800, 1000 s/mm²). Other parameters of IVIM were as follows: TR/TE = 2500/70 ms, FA = 90, FOV = 230 x 230 mm², matrix = 128 x 126, slice thickness = 5 mm, slices = 11, average = 1. The signal equation: S = S0·[(1-f) exp(-BD*)+f exp(-bD)] was fitted to obtain f pixel-by-pixel. The f and D were measured in the three hot spot regions-of-interest in each map. Histopathologic vascular density was measured in three microscopic fields (x200) of the most intense vascularization on CD-31-immunostained histopathologic specimens. Statistical analysis was performed with the Pearson correlation coefficient and receiver operating characteristic (ROC). A p value less than .05 was considered significant.

RESULTS
The f-value (4.2-27.1%) significantly correlated (r = 0.72, P = 0.0018) with vascular density (0.60-13.4%). The f of HGTs (19.1±4.6%) was significantly higher than LGTs (7.7±4.0%; P = 0.0047). The D of HGTs (0.93±0.34 x 10^-3/mm²) was significantly lower than LGTs (1.70±0.34 x 10^-3/mm²; P = 0.0032). ROC analysis showed high Az values with f (0.94) and D (0.96) without a statistically significant difference (P = 0.74).

CONCLUSION
The f-value derived from IVIM significantly correlated with vascular density of pediatric brain tumors. Both f and D parameters could discriminate HGTs from LGTs.

CLINICAL RELEVANCE/APPLICATION
Using IVIM, we could simultaneously evaluate flow and diffusivity in pediatric brain tumors. The f-value derived from IVIM significantly correlated with vascular density. Both f and D could discriminate HGTs from LGTs.
For differentiation between posterior fossa PAs with and without gangliocytic differentiation, location and minimum rADC may be a useful adjunct to histopathologic diagnosis, which is subject to sampling error.

**PURPOSE**
Ependymoblastoma (EBL), ependymoma (EP), and primitive neuroectodermal tumors of the central nervous system (CNS-PNET NOS = not otherwise specified) are pediatric brain tumors that can be differentiated by histopathology in the clinical setting. Recently, we first described specific MRI features of EBL. In this study, we compare standardized MRI characteristics of EBL with EP and CNS-PNET NOS in a series comprising of 22 patients in each group.

**METHOD AND MATERIALS**
We systematically analyzed the initial cranial MRI scans at diagnosis according to 25 standardized criteria, and paired comparison was performed for EBL and EP, as well as for EBL and CNS-PNET NOS. All 66 cases of this multi-center study were centrally reviewed regarding histopathology, MR imaging and multimodal therapy.

**RESULTS**
We found differences between EBL and EP regarding age at diagnosis, MR signal intensity, tumor margin and surrounding edema, presence and size of cysts, and contrast enhancement pattern. Although MRI appearance of EBL shares many features with CNS-PNET NOS, we revealed significant differences in terms of age at diagnosis, tumor volume and localization, tumor margins, edema, and contrast enhancement.

**CONCLUSION**
We systematically analyze and compare MRI characteristics of pediatric EBL with EP and CNS-PNET NOS in a series of 22 centrally reviewed cases of each group. A definite differentiation of these entities with MRI seems to be difficult; however, we identify particular imaging features that might help distinguishing these histologically distinct tumor types.

**CLINICAL RELEVANCE/APPLICATION**
This is the first study that systematically compares multiple parameters of MR imaging in pediatric EBL with findings in EP and CNS-PNET NOS. Since EBL is very rare, our data provides important information that might help differentiating EBL from other pediatric brain tumor entities in the clinical setting.

**VSPD11-06 Quantitative Approach to the Posterior Cranial Fossa and Cranio-cervical Junction in Asymptomatic Children with Achondroplasia**

- Giuseppe M. Di Lella, MD, Rome, Italy
- Giuseppe M. Di Lella, MD, Rome, Italy

**PURPOSE**
Achondroplasia, the best-known form of congenital dwarfism, is caused by a disturbance of endochondral bone formation. We proposed a MRI-based quantitative morpho-volumetric approach to the posterior cranial fossa and cranio-cervical junction to understand posterior cranial fossa changes responsible of ventriculomegaly and life-threatening medullary compression.

**METHOD AND MATERIALS**
We analyzed brain MRI of 12 children with a diagnosis of achondroplasia (mean age 39 ± 16 months) and no surgical treatment.

**RESULTS**
All patients showed synostosis of sphen-occipital synchondroses while six patients showed synostosis of anterior and posterior intra-occipital synchondroses, cervical myelopathy without swelling cord. Compared to control group, clivus and exocciput lengths, L-L and A-P diameters of the foramen magnum, foramen magnum area and jugular foramina area were significantly reduced; supraocciput length, tentorial angle, PCFV, PCFBV, CeV, Ve, brainstem volume and supratentorial ventricular system volume were...
significantly increased (p<0.05) while PCFV/PCFBV ratio, the subarachnoid spaces volume of the PCF and IV ventricle volume were not significant (p>0.05).

CONCLUSION
The quantitative approach to the posterior fossa and cranio-cervical junction modifications shows a complex relationship among the maldevelopment of the posterior cranial fossa, the foramen magnum stenosis, the development of ventriculomegaly, and medullary compression.

CLINICAL RELEVANCE/APPLICATION
Posterior cranial fossa changes and foramen magnum stenosis should be evaluated together to the status of synchondroses in order to plan the prophylactic cervicomedullary decompression.

LEARNING OBJECTIVES
1) Understand the embryologic derangements behind the more common congenital spinal anomalies encountered in clinical practice.
2) Be able to apply a clinical-radiological classification to facilitate the interpretation of imaging studies of patients with spinal dysraphism.

ABSTRACT
Encouraging imaging studies on patients with congenital spinal anomalies can be intimidating for radiologists, particularly when pediatric imaging and/or neuroimaging are not a large part of your practice. A clinical-radiological classification system developed by Tortori-Donoto, et al (Neuroradiology, 2000), remains a valuable approach to correctly diagnosing these children, largely dividing entities into open or closed spinal dysraphism based on the absence or presence of overlying skin, respectively. Closed spinal dysraphism is further subdivided into those lesions that present with a subcutaneous mass versus those that do not. Lesions without a subcutaneous mass can be further subdivided into simple and complex, and may be associated with other cutaneous stigmata such as hemangioma, skin dimple, and/or focal hairy patch.

**SSA2-04 Evaluation of Tumor Volume and Target Volume Definition Based on Diffusion-weighted MRI in Radiotherapy of Non-small Cell Lung Cancer**

Sunday, Nov. 29 11:15AM - 11:25AM Location: S104A

Participants
The purpose of this study was to evaluate DWI of the thorax in determination of tumor volume and assessment of target volume for radiation therapy planning of non-small cell lung cancer (NSCLC) in comparison to a FDG-PET-CT based approach.

**METHOD AND MATERIALS**

13 pts with NSCLC and indication for primary radio(-chemo)therapy were prospectively evaluated with both MRI and PET-CT. 13 primary tumors with UICC stages I (4 pts.), II (1 pt.), IIIA (3 pts.) and IIIB (5 pts.) were evaluated. For MRI a respiratory gated T2-weighted sequence in axial orientation and non-gated DWI (b = 0, 800, 1400 and ADC map) were acquired on a 1.5 T scanner (Siemens, Magnetom® Aera). FDG PET-CT was performed as part of the routine staging. Both MR and PET-CT images were coregistered on a radiation treatment planning system (Phillips, Pinnacle3®). For the FDG-PET-CT data a semiautomatic contouring of the gross tumor volume (GTV) of the primary tumor based on a "source-to-background"-Algorithm was applied. For DWI and the T2w sequences a visual definition of the GTV was performed. Beside a statistical comparison of the GTV an evaluation of the target volume based on the "Hausdorff-Distance" (HD) and the "Dice Similarity Coefficient" was performed.

**RESULTS**

The median values (+ range) of the GTV for PET-CT and MRI (DWI and T2w imaging) did not differ significantly (PET-CT 69 ml (3 - 229 ml), DWI 71 ml (4 - 361 ml), T2w 65 ml (5 - 350 ml)). The measured tumor volumes with all three techniques showed a highly significant correlation (PET/CT vs. DWI: r=0.97; PET/CT vs. T2w imaging: r=0.89; DWI vs. T2 imaging: r=0.92; p < 0.0001). However in 9 out of 13 cases DWI showed a larger volume as compared with the FDG-PET data (mean difference 29.8% ± 19.5%). Comparing PET-CT and DWI a good agreement regarding the spatial target volume was found (HD: 2.5 ± 1.1 mm; DC 0.65 ± 0.08), which showed a tendency of decreased agreement with increasing tumor volumes.

**CONCLUSION**

FDG-PET-CT and MR based GTV definition overall shows a good agreement, especially regarding the spatial-topographic tumor localization. Tumor volumes may differ considerable in a particular case and further studies have to evaluate the added value of DWI in radiotherapy planning.

**CLINICAL RELEVANCE/APPLICATION**

Based on our initial findings DWI in radiation therapy planning can give important additional information and should be evaluated in larger scale studies.

**SSA22-05 The Impact of Respiratory Movement on Local Recurrence in Patients with Stage I Non-Small Cell Lung Cancer in the Treatment of Intensity Modulated SBRT**

**ABSTRACT**

Purpose/Objective(s): Phase II study of intensity-modulated stereotactic body radiotherapy (SBRT) using compensated filter for patients with stage I NSCLC was conducted. In this study, an internal target volume (ITV) was set to compensate for respiratory uncertainty under restriction of respiratory movement. The purpose of this study was to evaluate outcomes and prognostic factors when patients with stage I NSCLC were treated using this method.

Materials/Methods: This study was approved by our facility’s ethical board. All patients provided written informed consent. Eligible criteria included the following: 1. patients who were unsuitable for surgery, 2. cytologically or histologically proven NSCLC, a tumor highly suspected of having NSCLC due to high accumulation in positron emission tomography or tumor growth rates of 25% compared to a previous image, 3. a clinical stage of T1-2N0M0 according to the 7th UICC TNM classification. To restrict the respiratory movement, the abdomen was pressed by a custom-made plastic immobilization belt. While wearing this device, a planning CT was taken during the inspiratory and expiratory phases, and the ITV was determined as the volume which covered the CTV in both phases. A compensator-based intensity modulated SBRT dose of 75 Gy given in 30 fractions was prescribed to PTV.

Results: Forty-three patients with a total of 45 tumors at stage I NSCLC who underwent SBRT were entered into this study at Tokyo Medical University between March 2012 and March 2014. The median age of patients was 80 years (range, 49-90), and the male/female ratio was 28/15. Of the 45 tumors, 29 were T1, 16 were T2. Eighteen tumors were located in the upper lobe, 6 in the middle lobe and lingual segment, and 21 in the lower lobe. Regarding histological type, 12 tumors was identified as adenocarcinoma, 9 as squamous cell carcinoma, 8 as non–small-cell carcinoma and 16 were unidentified. During follow-up (median 15 months), actuarial local progression-free rates at 1-year and 2-years were 92.3% (95% confidence interval [CI] 78.0 to 97.5%) and 87.2 % (95% CI, 67.5 to 95.3%), respectively. The actuarial local progression-free survival rate in patients with an ITV 30 ml larger than their GTV was significantly lower than those with a difference of 30 ml or less (p=0.029). Tumor histology, tumor location and minimum dose of ITV had no significant effect on local progression-free survival rates by univariate analysis. By multivariate analysis, an ITV minus GTV volume larger than 30 ml (hazard ratio = 11.2, p = 0.04) was a statistically significant indicator of poor local progression-free survival rates. Minimum dose of ITV and tumor location were not significant.

Conclusion: A large volume of ITV minus GTV was a negative prognostic factor for local progression in SBRT, which suggested that in instance of high respiratory movement, special technique of respiratory gaiting or tumor-tracking may be necessary.
SSA22-06  Comparison of Dose Distributions Calculated with Different Dose Calculation Algorithms in Pulmonary Lung Lesions in Order to Analyze the Influence of Different Algorithms on the Dose Prescription

Sunday, Nov. 29 11:35AM - 11:45AM Location: S104A

PURPOSE
To introduce more accurate algorithms like Monte Carlo (MC) into the clinical routine, an adjustment of the currently used EPL or PB dose prescription is required. The goal of this study was to find the dose prescription adjustment when switching from PB to MC in iPlan and from EPL to MC in MultiPlan, respectively. For that reason dose distributions calculated with the different algorithms were analyzed for patients with malignant pulmonary lung lesions with different tumor size and location.

METHOD AND MATERIALS
For 124 lung lesions, treated between 2010 and 2014 at the Novalis TX (Varian Medical Systems) and at the CyberKnife (Accuray), dose distributions were initially calculated with PB and retrospectively re-calculated with MC in iPlan. In the same way, dose distributions were initially calculated with EPL and retrospectively re-calculated with MC in MultiPlan. We compared the PB with the MC dose distribution within iPlan as well as the EPL with the MC dose distribution within MultiPlan. The following parameter were compared: minimum dose to 99% (D99), 95% (D95) and Dmean of the different target volumes (GTV, CTV, ITV, PTV); prescription isodose volume (PIV), the heterogeneity index (HI) and Dmean as well as Dmax to the organs at risk (OARs). Based on changes in D99, D95 and mean PTV dose, the prescription dose was converted from PB to MC and from EPL to MC, respectively.

RESULTS
So far, 64/124 lesions were evaluated (PB n=52, EPL n=12). The D99 and D95 to the PTVs were reduced when using MC in comparison to PB and EPL. Reduction was larger for peripheral tumors than for central tumors (up to 25% vs. 5%). Maximum in reduction was seen in small peripheral lesions, i.e. the PIV can be reduced up to 95% (PB volume 8.36ccm vs. MC volume 0.37ccm). Based on D95, for small peripheral lesions the PB prescription of 5x12Gy has to be reduced to 5x9.5Gy for MC. The mean and maximum dose to OARs decreased when using MC in comparison to EPL or PB.

CONCLUSION
Our preliminary results confirm that the dose prescription has to be adjusted when switching from PB or EPL to MC. Furthermore we found, that the adjustment is different when switching from PB to MC in iPlan in comparison to switching from EPL to MC in MultiPlan.

CLINICAL RELEVANCE/APPLICATION
Future trials will show, if the more accurate dose calculation by MC might increase the probability of tumor control and/or might lower the toxicity.

SSA22-07  Dynamic Contrast-enhanced Perfusion Area-Detector CT Assessed by different Mathematical Models vs. FDG-PET/CT: Capability for Therapeutic Outcome Prediction in Non-Small Cell Lung Cancer Patients with Chemoradiotherapy

PURPOSE
To directly compare the capability for therapeutic outcome prediction between dynamic first-pass contrast-enhanced (CE-) perfusion area-detector CT (ADCT) assessed by different mathematical methods and FDG-PET/CT in non-small cell lung cancer (NSCLC) patients treated with chemoradiotherapy.

METHOD AND MATERIALS
53 consecutive Stage IIB NSCLC patients underwent PET/CT, dynamic CE-perfusion ADCT, chemoradiotherapy, and follow-up examination. In each patient, therapeutic outcomes were assessed as therapeutic effect based on RECIST guideline, disease free interval and overall survival. Then, all patients were divided into two groups as follows: 1) complete or partial response (CR+PR) and
2) stable and progressive diseases (SD+PD) groups. In this study, total tumor perfusion (TPPDMS) and tumor perfusions from pulmonary (TPPDMS) and systemic (TPSDMS) circulations by dual-input maximum slope method, extraction fraction (EF) and distribution volume (DV) by Patlak plot method, tumor perfusion (TPSMS) by single-input maximum slope method, and SUVmax were assessed at each targeted lesion, and averaged to determine final values in each patient. To compare the capability for distinguishing CR+PR from SD+PD groups, ROC analyses were performed. Finally, disease free interval and overall survival between responders and non-responders were assessed by indexes as having no significant differences for differentiation capability on ROC analyses were compared by Kaplan-Meier method followed by log-rank test.

RESULTS

Area under the curves (AUs) of TPPDMS (Az=0.81), TPSDMS (Az=0.85) and SUVmax (Az=0.84) had significantly larger than that of TPPDMS (Az=0.69, p<0.05). On disease free interval and overall survival assessments, responders had significantly longer disease free interval and overall survival than non-responders on TPSDMS (disease free: p=0.002, overall: p=0.001), TPSMS (disease free: p=0.004, overall: p=0.03) and DV (disease free: p=0.03, overall: p=0.04).

CONCLUSION

Dynamic first-pass CE-perfusion ADCT provide a few good predictors, and have better potential than PET/CT for therapeutic outcome prediction in NSCLC patients treated with chemoradiotherapy.

CLINICAL RELEVANCE/APPLICATION

Dynamic first-pass CE-perfusion ADCT provide a few good predictors, and have better potential than PET/CT for therapeutic outcome prediction in NSCLC patients treated with chemoradiotherapy.

SSA22-08 Impact of Thoracic Radiation (TRT) on Survival of Extensive-Stage Small Cell Lung Cancer (ES-SCLC): A Singapore Population-Based Outcome Study

ABSTRACT

Purpose/Objective(s): Randomized studies have shown that TRT improved survival outcomes in patients with ES-SCLC responding to first line chemotherapy. This retrospective cohort study aims to evaluate the use of TRT and its impact on survival.Materials/Methods: All patients diagnosed with ES-SCLC without brain metastases in the only two Singapore national cancer centers from 2003 to 2010 were identified using the institutions’ pathology registries. We linked the treatment records to the national death registry. Demographic and clinical factors associated with the use of TRT were identified. Propensity score analysis was used to analyze the use of TRT on survival.Results: 59 of 224 patients were identified to receive TRT. The proportion of patients treated with TRT increased from 27% in 2003 to 38% in 2005 and decreased to 21% in 2010. Using an a/b ratio of 10 for tumor control, the median equivalent dose in 2 Grays (Gy) per fraction is 32.5Gy (range 4.7Gy to 60Gy). Patients treated with prophylactic cranial irradiation (adjusted odds ratio [OR] 4.85; 95% Confidence Interval [CI] 1.33 to 17.69, P = 0.017) or who had progressive disease after first line chemotherapy (adjusted OR 5.25; 95% CI 1.13 to 24.38, P = 0.034) were more likely to receive TRT. Controlling for demographic and clinical characteristics, TRT was associated with lower risk of death (Hazard ratio 0.48; 95% CI 0.34 to 0.67, P Conclusion: TRT has been not widely adopted in the treatment of ES-SCLC in Singapore and may be associated with improved survival. A larger population based outcome study to validate the survival benefit of thoracic radiation is warranted.

SSA22-09 A Retrospective Evaluation of Stereotactic Body Radiation Therapy for Pulmonary Oligometastases in a Multicenter Study

ABSTRACT

Purpose/Objective(s): Oligometastases was divided into sync-oligometastases and oligo-recurrence, the difference being that the primary site of oligometastases was uncontrolled (sync-oligometastases) or controlled (oligo-recurrence). The purpose of this study was to evaluate treatment outcomes after stereotactic body radiotherapy (SBRT) for pulmonary oligometastases.Materials/Methods: A total of 96 patients (65 males and 31 females) who received SBRT for pulmonary oligometastases between January 2004 and April 2014 at 4 high-volume institutions in Japan were enrolled in this retrospective
study. The primary sites were the colorectum (n=25), lung (n=24), head and neck (n=8), and others (n=39). Ten cases were sync-
oligometastases, 79 cases were oligo-recurrences and 7 cases were unclassified oligometastases. The median disease-free interval
(DFI) between initial therapy and SBRT was 24 months (range, 0-246 months). The median prescribed BED was 105.6 Gy (range,
75-134.4 Gy). Overall survival (OS), local control rate (LCR) and relapse-free survival rate (RFS) were calculated using Kaplan-Meier
curves, and the log-rank test was used to compare the curves. Multivariate analysis for RFS was performed using a Cox
proportional hazards model. Statistical significance was set at p Results: The median follow-up periods were 21 months (range, 1-
119 months) for all patients. The 3-year OS, LCR and RFS rates were 52%, 75% and 25%, respectively. Radiation pneumonitis of
grade 3 was found in 2 patients and gastrointestinal toxicity of grade 4 was found in 1 patient. No grade 5 toxicity occurred. The
3-year RFS for sync-oligometastases was 0% and that for oligo-recurrence was 28% (Figure, p Conclusion: In SBRT for pulmonary
oligometastases, control of the primary site is a significant prognostic factor for RFS.
Molecular Imaging Profiling of Treatment Effects in Experimental Multiple Sclerosis

PURPOSE

Treatment effects of interferon beta (IFN) and glatiramer acetate (GA), two first-line agents used in multiple sclerosis (MS), are similar as evaluated by conventional MRI. We imaged these two drugs with MPO-Gd, an activatable molecular MR probe specific to myeloperoxidase (MPO), an enzyme secreted by pro-inflammatory myeloid cells, to better profile and study their effects on the innate immune response in vivo.

METHOD AND MATERIALS

Thirty-five female SJL mice were injected with proteolipid protein to induce experimental autoimmune encephalomyelitis, a mouse model of MS, and treated with IFN (1 μg/day), GA (150 μg/day), MPO inhibitor ABAH (0.8 mg/day), or saline. Mice underwent MRI at 4.7T with MPO-Gd at disease peak (day 12). Lesion volume, number, contrast-to-noise ratio (CNR), and total MPO-Gd enhancement were quantified on delayed images. Mechanistic in vitro experiments were performed.

RESULTS

CNR (MPO activity in vivo) was decreased with ABAH and IFN, but not with GA. Lesion volume, lesion number, and total MPO-Gd enhancement was decreased with all three agents (Fig., A-B). These findings suggest that IFN may have the imaging signature of an MPO inhibitor. However, direct enzymatic inhibition was only found with ABAH, and not with IFN or GA (C). When primary neutrophils were stimulated to secrete MPO, IFN decreased activity of the MPO enzyme, similar to ABAH (D), while GA did not have a similar effect (D). When neutrophils were incubated with IFN, increased superoxide anion production (as measured by dihydroethidium [DHE] fluorescence) was detected (E). Inhibition of superoxide anion production by apocynin resulted in the restoration of MPO activity from stimulated neutrophils (F). Spectrophotometry revealed that IFN-mediated superoxide anion production abolished absorbance of MPO at 430 nm, consistent with irreversible destruction of the iron-containing prosthetic group (G).

CONCLUSION

Molecular imaging profiling with MPO-Gd reveals differential treatment effects of the two first-line drugs used in the treatment of MS (H), and led to the discovery of a novel mechanism of action of IFN: IFN triggers superoxide anion production in myeloid cells to irreversibly inactivate MPO.

CLINICAL RELEVANCE/APPLICATION

Molecular imaging profiling with imaging agents that probe the immune response could open up a new avenue to study the effects of current and future novel therapeutic drugs for MS.

Microtubule Stabilization Therapeutic Improves Cognition and Acutely Increases Axonal Transport on Manganese-enhanced MRI in Aged Mice with AD Pathology

PURPOSE

The purpose of this study was to evaluate the effect of a microtubule stabilization therapeutic on cognitive function and axonal transport in aged mice with Alzheimer's disease (AD) pathology.

METHOD AND MATERIALS

Aged C57BL/6 mice were divided into two groups: control (saline) and treatment (microtubule stabilizer). Mice underwent behavioral testing and manganese-enhanced MRI at baseline and at various time points post-treatment. Changes in cognitive function were assessed using standard cognitive tests, while MRI was used to evaluate axonal transport.

RESULTS

Behavioral testing revealed significant improvements in cognitive function in the treatment group compared to the control group (Fig. A-B). Axonal transport was also increased in the treatment group as indicated by the enhanced manganese signal on MRI (Fig. C-D).

CONCLUSION

The microtubule stabilization therapeutic showed promising effects on cognitive function and axonal transport in aged mice with AD pathology, suggesting potential therapeutic benefits in the management of AD.

CLINICAL RELEVANCE/APPLICATION

The results of this study highlight the potential of microtubule stabilization therapies in improving cognitive function and axonal transport in AD, which could lead to the development of novel therapeutic strategies for AD.
PURPOSE
Previously we reported increased axonal transport in young mice transgenic (Tg) for Alzheimer's disease (AD) after intranasal administration of a microtubule-stabilizing therapeutic, paclitaxel using MRI with manganese (MEMRI). In this study we administered paclitaxel to AGED 3xTg-AD mice with established pathology from 10-18 mos and hypothesized that cognition would improve and be associated with increased axonal transport.

METHOD AND MATERIALS
Mice, (3xTg-AD n=10, age=44wks) were treated by intranasal lavage with paclitaxel (TAX) (0.6 mg/kg) or 0.9% saline (SAL) in 5 μl per nostril at intervals of 2wks. MEMRI was obtained after first treatment to assess acute effect on transport. Scanning (14T Bruker MR: MDEFT, TR/TE: 5000ms/1.9ms, 0.140x0.140x0.25mm3) pre and immediately after treatment occurred at 100 min. and from 370-400 min after delivery of 5 μl of 1M MnCl2 intranasally. Images were coregistered stereotactically aligned and normalized to a mouse atlas. Tracer kinetic analysis based on dispersion model was used to estimate transport. At 56 wks after 5 treatments, mice were tested in radial water tread maze for memory deficits and compared to age-matched WT (n=5) and at 75 wks after 11 treatments, anxiety was assessed by elevated plus maze.

RESULTS
At 10 mos, 3xTg-AD have amyloid and neurofibrillar tangles. There was a significant acute effect of TAX on transport in the olfactory tract. Transport rates decreased slightly in SAL (-13%) in the 3wk interval between MEMRI scans however TAX increased (>100%) transport at 24hrs after administration (p<0.05). Cognition was tested in the water tread maze (memory) and elevated plus maze (anxiety). TAX had improved memory as compared to SAL and not significantly different from WT (Day 5, 36% dec, 143.8±43 vs 91.5±77s and Day 12, 22% dec, 138.3±52 vs 107.7±75s for SAL vs. TAX, p<0.05). Paired t-tests comparing TAX vs SAL showed no significant differences in Mn2+ uptake indicating delivery thru activity-dependent Ca2+ channels was not affected by treatment.

CONCLUSION
MEMRI indicated that paclitaxel has an acute effect on axonal transport processes in AD mice. Paclitaxel also improved cognition and anxiety in AD mice when administered after pathology was well-established.

CLINICAL RELEVANCE/APPLICATION
Microtubule-stabilizing drugs present an exciting new therapeutic option for Alzheimer's disease.

Whole-Brain, Volumetric MR Spectroscopic Profiles Identify Infiltrating Glioblastoma Margin for Fluorescence-Guided Surgery

PURPOSE
Glioblastoma (GBM) resection based on T1W-contrast enhanced MRI (T1W-CE) results in high rates of local recurrence due to tumor infiltration beyond contrast enhancing margins. MR spectroscopic imaging (MRSI) maps are thought to identify tumor infiltration outside of T1W-CE regions more specifically than T2-FLAIR. Thus, coupling preoperative MRSI with real-time fluorescence-guided surgery (FGS) using 5-aminolevulinic acid (5-ALA) may allow the maximal removal of tumor beyond the enhancing margin.

METHOD AND MATERIALS
In a trial for new and recurrent GBM (n=20 patients), 3D whole-brain MRSI volumes, including choline (Cho), creatine (Cr), and N-acetylaspartate (NAA) maps, were acquired and used for surgical planning in patients receiving FGS. Biopsies were collected from regions with elevated Cho/NAA before bulk resection using 5-ALA fluorescence. Fluorescence of resected tissue was quantified ex vivo with a hand-held spectrometer, and metabolic data was sampled from MRSI volumes using an 8 mm³ region-of-interest centered at the point of tissue extraction. Samples were stained for SOX2, a tumor-specific marker, and analyzed to quantify tumor infiltration using an automated histology image analysis tool. Semi-automated tumor segmentation was used to evaluate extent-of-tumor resection (EOR) (Cordova et al. 2014).

RESULTS
One-hundred percent of tissue samples from metabolically abnormal regions, even those devoid of T2 abnormality, contained SOX2 positive cells (range: 3 - 96% of cells). Cho/NAA, Cho/Cr, and Cho showed strong, statistically significant correlations with the proportion of SOX2-positive cells (p = 0.70, 0.66, and 0.60, respectively; p < 0.05). Ex vivo tissue fluorescence showed a weaker yet significant correlation with Cho/NAA and Cho (p = 0.365 and 0.404; p<0.05). Median EOR in MRSI/5-ALA cases was 97.5% whereas that in a concurrent study using FGS alone was 94.2%.
CONCLUSION
This is the first time that 5-ALA-induced fluorescence has been shown to correlate with MRSI-derived metabolic markers in brain tumors. The correlation of MRSI abnormality with histopathology and quantitative intraoperative fluorescence supports the use of MRSI for identifying regions of tumor infiltration outside of T1W-CE.

CLINICAL RELEVANCE/APPLICATION
As MRSI is independent of contrast diffusion, it defines tumor infiltration more precisely than T1W-CE; and when combined with FGS, results in more complete resections that may extend patient survival.

SSA12-04  Motexafin Gadolinium (MGd) - Enhanced MR and Optical Imaging of Rat Gliomas for Potential Intraoperative Determination of Tumor Margins

Sunday, Nov. 29 11:15AM - 11:25AM Location: S504CD

Participants
Longhua Qiu, Seattle, WA (Presenter) Nothing to Disclose

Xiaoyuan Feng, MD, Shanghai, China (Abstract Co-Author) Nothing to Disclose
Xiaoming Yang, MD, PhD, Seattle, WA (Abstract Co-Author) Nothing to Disclose

PURPOSE
To investigate the possibility of using motexafin gadolinium (MGd)-enhanced molecular MR imaging and optical imaging to identify the genuine margins of rat gliomas.

METHOD AND MATERIALS
Rat glioma model was created by inoculating C6 glioma cells in right caudate nucleuses of male Sprague-Dawley rats (160g ± 20g). Thirty six rats with tumors were randomized into six groups (n=6/group). Five groups were euthanized at different time points of 15, 30, 60, 120 and 240 minutes after intravenous administration of 6-mg/kg MGd respectively, while one group received saline as a control. After a craniotomy, ex vivo optical imaging was performed to identify the tumors featuring as MGd-emitting red fluorescence. Then, the whole brains were harvested for ex-vivo T1-weighted MRI (T1WI). Optical photon intensities and MRI signal-to-noise ratio (SNR) were quantified for plotting the times to photon/SNR curves. Tumor extent was demarcated on both optical and MR imaging. Subsequently, confocal microscopy of brain tissues was performed to confirm the intracellular uptake of MGd by tumor cells and correlate the tumor margins determined on both optical and MR images.

RESULTS
Fluorescent optical imaging could sensitively detect the deep-seated tumors with red fluorescence in rat brains and clearly outlined the tumor margins. T1WI showed the tumors heterogeneous enhancement. Both the photon intensity and the maximal enhancement on T1WI reached the peak at 15 minutes after MGd administration, with a continuing tumor visibility lasting for 2-4 hours. Confocal microscopy confirmed the exclusive accumulation of MGd in tumor cells which was well correlated with imaging findings.

CONCLUSION
Both MGd-enhanced optical imaging and molecular MR imaging can sensitively determine rat glioma tumor margin within the optimal time window of 15~30 minutes post-MGd administration, which pose the potential clinical application for aiding the complete removal of gliomas at a hybrid surgical setting with intraoperative optical and MR imaging capabilities.

CLINICAL RELEVANCE/APPLICATION
MGd-enhanced imaging poses a potential clinical application for aiding the complete removal of gliomas at a hybrid surgical setting with intraoperative optical and MR imaging capabilities.

SSA12-05  Generation of a Bispecific Antibody for Combined EGFR/CD105 Targeting of High-Grade Gliomas

Weibo Cai, PhD, Palo Alto, CA (Abstract Co-Author) Nothing to Disclose

PURPOSE
Our aim was to design and generate a heterodimer [Bs-F(ab')2] using two mAb Fab fragments for dual-targeting of epidermal growth factor receptor (EGFR) and CD105. The synergistic targeting properties of Bs-F(ab')2 were investigated in vitro/in vivo.

METHOD AND MATERIALS
Bs-Fab'2 was synthesized by reacting two mAb fragments (Cetuximab Fab and TRC105 Fab) derivatized with the 'Click' chemistry pair tetrazine/trans-cyclooctene. Bs-Fab'2 was purified by size exclusion chromatography, conjugated to NOTA, and labeled with 64Cu for positron emission tomography (PET). In vitro and in vivo dual-receptor binding studies were performed in a U87MG human
RESULTS

Purified Bs-F(\text{ab}')\text{2} was confirmed by SDS-PAGE (~100 kDa, >90% pure), whereas the two Fab fragments were each at ~50 kDa. Flow cytometry showed an enhanced fluorescence signal for the heterodimer compared with either Fab. PET of U87MG tumor bearing mice with 64Cu-NOTA-Be-F(\text{ab}')\text{2} revealed a strikingly higher tumor uptake (32.0±6.9, 47.5±6.7, 46.0±3.3 and 44.1±9.4 %ID/g at 3, 15, 24, and 36 h postinjection, respectively; n=3) compared to those observed with 64Cu-NOTA-Cet-Fab and 64Cu-NOTA-TRC105-Fab (both <15%ID/g). Injection of a blocking dose (100mg/kg) of Cetuximab or TRC105 prior to the administration of the tracer resulted in a significantly reduced tumor uptake of 64Cu-NOTA-Be-F(\text{ab}')\text{2}, which confirmed that Bs-F(\text{ab}')\text{2} tumor-uptake was mediated by both EGFR and CD105 expression. Owing to the low tracer uptake in non-target organs (e.g. liver and kidney), we attained excellent tumor-to-normal tissue contrasts.

CONCLUSION

We report the first successful dual-targeting of EGFR and CD105, with a "click" heterodimer featuring two mAb Fab fragments, which led to synergistic enhancement of tumor uptake over either Fab alone. These results may improve future cancer diagnosis and therapeutic efficacy.

CLINICAL RELEVANCE/APPLICATION

Combined EGFR/CD105-targeting provides increased tumor-targeting efficacy and specificity, which may ultimately lead to better diagnostic sensitivity and increased tumor cytotoxicity.

SSA12-07 MRI Contrasts Induced by Direct Saturation: Demonstration in the Central Nerve System

Sunday, Nov. 29 11:45AM - 11:55AM Location: S504CD

Participants

Rongwen Tain, PhD, Chicago, IL (Presenter) Nothing to Disclose
Feliks Kogan, PhD, Stanford, CA (Abstract Co-Author) Nothing to Disclose

Kejia Cai, PhD, Chicago, IL (Abstract Co-Author) Nothing to Disclose

PURPOSE

A frequency selective saturation RF pulse across a broad frequency range produces a Z-spectrum. This Z-spectrum receives contributions from components mainly including direct saturation (DS) of bulk water, magnetization transfer, chemical exchange saturation transfer, and Nuclear Overhauser Enhancement. When a weak saturation regime is applied, such as B1rms< 50 Hz and duration < 500 ms, the Z-spectrum is mainly attributed to the DS spectrum, characterized by a Lorentzian-shape. The DS magnitude at a given frequency offset has been used to measure iron content in brain. Additionally, the position of maximum DS has been exploited to map B0 field variations (ΔB0). In this study, we investigate additional contrasts revealed by analyzing DS spectrum.

METHOD AND MATERIALS

This study was performed under an approved IRB protocol. DS spectra within ±1 ppm were acquired from the brain and cervical spinal cord of healthy subjects at 3T scanner with a 32 channel head-coil and a 16 channel head and neck spine coil, respectively. The pulse sequence consists of a pre-saturation pulse (B1rms = 12.2 Hz for brain, 24.4 Hz for spinal cord, 200 ms) followed by a 2D single-shot SPGR readout. The DS data was fitted pixel by pixel with a Lorentzian function to produce B0 field, DS line-width, and DS magnitude maps. In addition, simulations with Bloch equations were performed to correlate with experimental data.

RESULTS

Beside the ΔB0 map, the Lorentzian fitting of data obtained from both brain and spinal cord was used to produce new maps based on the DS line-width and magnitude. In the brain and spinal cord respectively, the DS line-width of gray matter is slightly narrower than that of the white matter. As expected, CSF gave the narrowest line-widths. DS amplitude was reversed. Simulation further showed that DS line-width is positively proportional to 1/T2 and inversely proportional to 1/T1. DS magnitude was found to be proportional to proton density.

CONCLUSION

Two quantitative contrasts (DS line-width and magnitude) that reflect tissue relaxation rates and proton density have been demonstrated in the human CNS tissues.

CLINICAL RELEVANCE/APPLICATION

The discovered contrasts induced by DS MRI have the clinically potential for characterization of normal and pathological tissues.

SSA12-08 CD146-based Noninvasive ImmunoPET Imaging of High-grade Gliomas

Sunday, Nov. 29 11:55AM - 12:05PM Location: S504CD

Participants

Reinier Hernandez, MSc, Madison, WI (Presenter) Nothing to Disclose
Yunan Yang, Madison, WI (Abstract Co-Author) Nothing to Disclose
Stephen Graves, Madison, WI (Abstract Co-Author) Nothing to Disclose
Robert J. Nickles, PhD, Madison, WI (Abstract Co-Author) Nothing to Disclose
Weibo Cai, PhD, Palo Alto, CA (Abstract Co-Author) Nothing to Disclose

PURPOSE

The goal of this study is to establish CD146 as a novel target for in vivo immunoPET imaging of mice bearing orthotopic high-grade gliomas (HGG).

METHOD AND MATERIALS
An improved immunization approach was used to generate YY146, a murine anti-CD146 monoclonal antibody. RT-PCR, western blot, flow cytometry, and immunofluorescence staining studies were conducted to determine in vitro CD146 expression. Subcutaneous (s.c.) U87MG human glioblastoma (CD146+) and PC3 human prostate cancer (CD146-) tumors were induced in athymic nude mice. Additionally, orthotopic U87MG tumors were generated in nude mice and its progression monitored by T2-weighted MRI. YY146 was conjugated to p-SCN-Bn-NOTA and radiolabeled with 64Cu. Sequential PET scans, blocking, histological, and biodistribution studies were carried out to determine in vivo CD146 specificity of 64Cu-NOTA-YY146.

RESULTS
Flow cytometry demonstrated that chelator conjugation to YY146 did not compromise its CD146-binding affinity/specificity. 64Cu-NOTA-YY146 was obtained with high radiochemical purity (>95%) and specific activity, in yields surpassing 90%. MicroPET imaging studies revealed an elevated and persistent uptake of 64Cu-NOTA-YY146 in U87MG (CD146+) s.c. xenografts which peaked at 13.7±0.7 %ID/g, 48h post-injection (n=3). In contrast, significantly lower accumulation was observed in PC3 (CD146-) tumors (<5 %ID/g). Excellent tumor homing was observed from PET/CT imaging of orthotopic U87MG tumors, where 64Cu-NOTA-YY146 was able to infiltrate the brain and accumulate in tumorous tissue (21.5±3.5 %ID/g at 48h post-injection; n=5). The attained exquisite tumor-to-normal brain contrast allowed for the sensitive detection of small malignancies (~2 mm). Biodistribution, blocking experiments, as well as histological examination validated PET data, and confirmed the CD146 specificity of 64Cu-NOTA-YY146.

CONCLUSION
We successfully implemented noninvasive immunoPET imaging of in vivo CD146 expression in an orthotopic human glioblastoma cancer model. The high affinity and specificity of 64Cu-NOTA-YY146 envisages the potential of this novel mAb for targeted HGG diagnosis and therapy.

CLINICAL RELEVANCE/APPLICATION
Herein, we show for the first time that CD146 is a promising tumor-specific target for noninvasive in vivo imaging and targeted therapy of high-grade gliomas.

SSA12-09 The Expression of P2X7 Receptors in EPCs and Their Potential Role in the Targeting of EPCs to Brain Gliomas

Sunday, Nov. 29 12:05PM - 12:15PM Location: S504CD

Participants
Xiao Chen, Chongqing, China (Presenter) Nothing to Disclose
Weiguo Zhang, Chongqing, China (Abstract Co-Author) Nothing to Disclose
Jingqin Fang, Chongqing, China (Abstract Co-Author) Nothing to Disclose

PURPOSE
To investigate the functional expression of P2X7 receptors in EPCs, role of P2X7 receptors in proliferation and homing to glioma of EPCs.

RESULTS
We confirmed, for the first time, the expression of P2X7 receptors in rat spleen-derived EPCs. Activation of P2X7 receptors in EPCs by BzATP promoted cells proliferation and migration, rather than apoptosis. Compared to the group without BBG treatment, less transplanted EPCs homed to gliomas in the group with BBG treatment, especially integrated into the vessels containing tumor-derived endothelial cells in gliomas. Moreover, western blot showed that CXCL1 expression was downregulated in gliomas with BBG treatment, which meant P2X7 receptors suppression inhibited the homing of EPCs to gliomas through down-regulation of CXCL1 expression. Additionally, MTT assay and MRI revealed that P2X7 receptors exerted no significant promoting effect on C6 glioma cells proliferation, glioma growth and angiogenesis.

CONCLUSION
Taken together, our findings imply the possibility of promoting proliferation and targeting ability of transplanted EPCs to brain gliomas in vivo through P2X7 receptors, which may provide new perspectives on application of EPCs as a therapeutic and imaging probe to overcome antiangiogenic resistance for gliomas.

CLINICAL RELEVANCE/APPLICATION
Apply EPCs as a therapeutic and imaging probe to overcome antiangiogenic resistance for gliomas.
**Principles and Practice of 3D Printing**

**Sunday, Nov. 29 11:00AM - 12:30PM Location: S501ABC**

**Participants**
Frank J. Rybicki III, MD, PhD, Ottawa, ON (Moderator) Research Grant, Toshiba Corporation; Jonathan M. Morris, MD, Rochester, MN (Moderator) Nothing to Disclose

**LEARNING OBJECTIVES**
1) Learn the basics of 3D printing technologies. 2) Discuss how these can be used clinically. 3) Discuss the current limitations of this technology as it relates to health care. 4) Use case examples to define current uses of this technology in surgical and medical specialties.

**ABSTRACT**
3D printing/additive manufacturing is a growing industry. Within the medical field there is growing interest in this technology and its impact on patients lives. In this talk we will discuss the basics of 3D printing and how they can be incorporated into medical uses from surgical design of implants to anatomic modeling of complex surgery.

**Sub-Events**

**RCC11A 3D Printing for the Radiologist: A Primer and Introduction to Sessions**

Participants
Frank J. Rybicki III, MD, PhD, Ottawa, ON (Presenter) Research Grant, Toshiba Corporation;

**LEARNING OBJECTIVES**
1) To become familiar with 3D printing technologies. 2) To have an introduction of materials used to create 3D-printed anatomical models and how they can be used in medical applications. 3) To be exposed to the process of 3D printing and those realized and potential clinical benefits in radiology, stratified by organ section.

**ABSTRACT**
While advanced visualization in radiology is instrumental for diagnoses and communication with referring clinicians, there is an unmet need to render DICOM images as three-dimensional (3D) printed models capable of providing both tactile feedback and tangible depth information of both anatomic and pathologic states. 3D printed models, already entrenched in the non-medical sciences, are being rapidly embraced in medicine as well as in the lay community. Incorporating 3D printing from images generated and interpreted by radiologists presents particular challenges including training, materials and equipment, and guidelines. The overall costs of a 3D printing lab must be balanced by clinical benefits. The RSNA 2015 program includes 6 hours of didactic lectures that review and summarize numerous studies that support such benefits from 3D printing, as it is expected that the number of 3D printed models generated from DICOM images for planning intervention and fabricating implants will grow exponentially. The program also includes multiple hands-on courses that will enable radiologists, at a minimum, to become familiar with 3D printing software and hardware as it relates to our field.

**RCC11B 3D Printing Technologies**

Participants
Peter C. Liacouras, PhD, Bethesda, MD (Presenter) Nothing to Disclose

**LEARNING OBJECTIVES**
1) Understand the basic principle of Additive Manufacturing (3D Printing) and how it differs from subtractive technology. 2) Understand the principles of the software needed to convert Medical Images into three-dimensional printed models and what factors contribute to the quality of each model. 3) Become familiar with the different types of Additive Manufacturing (3D Printing) technologies.

**ABSTRACT**
This presentation will provide a novice to Additive Manufacturing the general knowledge applicable to the medical field. The basic principles of Additive manufacturing (3D Printing) will be discussed along with the different technologies which encompass the field. The steps of converting radiographic images into three-dimensional printable files and the differences between the multitude of additive manufacturing techniques will be the primary focuses.

**RCC11C Techniques for Current 3D Printing**

Participants
Gerald T. Grant, DMD, MS, Bethesda, MD (Presenter) Nothing to Disclose
RCC11D  3D Printing Software

Participants
Andreas Giannopoulos, MD, Boston, MA, (agiannopoulos1@partners.org) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To become familiar with common 3D printing software terminology and software capabilities. 2) To be acquainted with the line of software needed in transforming medical images to 3D printable files. 3) To appreciate the implementation of 3D printing software in everyday clinical practice.

ABSTRACT
3D printers cannot recognize DICOM images and further steps are necessary to make DICOMs readable by 3D printers. While adequately trained personnel can perform many of those steps, the role of the radiologist is essential to ensure that the model will be clinically useful. A variety of software packages for STL generation from medical imaging as well as software for 3D part manipulation, known as Computer-Aided Design (CAD), will be discussed. Basic technical terminology and commonly used techniques will be presented. Real life paradigms from own medical 3D printing experience will be provided.

RCC11E  3D Printing with Open Source Freeware

Participants
Michael W. Itagaki, MD, MBA, Seattle, WA (Presenter) Owner, Embodi3D, LLC

LEARNING OBJECTIVES
1) To become familiar with the steps of converting a medical imaging scan in standard Digital Imaging and Communications in Medicine (DICOM) format into a 3D printable medical model. 2) To become familiar with the free, open-source software packages that can perform each step.

ABSTRACT
This presentation will provide an overview of the basic steps of converting a medical scan into a 3D printed medical model, using free, open-source software for each required step. Conversion of computed tomography image data in Digital Imaging and Communications in Medicine (DICOM) format to stereolithography (STL) file format using the open-source software package 3D Slicer will be reviewed. Further manipulation of the STL file in preparation for 3D printing using the open-source software package Blender will also be discussed.

RCC11F  Implementing 3D Printing into a Clinical Practice

Participants
Jonathan M. Morris, MD, Rochester, MN (Presenter) Nothing to Disclose

ABSTRACT
3D printing/additive manufacturing is a growing industry. Within the medical field there is growing interest in this technology and its impact on patients lives. In this talk we will discuss how we incorporated this technology into a quaternary referral center as a real time clinical service. We will specifically discuss the advantages as well as limitations of this technology as it relates to the medical/surgical field. We will discuss "How we do it" and what resources are needed to develop a service. As the impact of this technology is growing we will also discuss what evidence will we need to have global acceptance as a clinical service and why it should be housed in radiology.
Data Collection, Organization and Analysis with Excel - A Hands-On Tutorial (Hands-on)

Sunday, Nov. 29 11:00AM - 12:30PM Location: S401AB

AMA PRA Category 1 Credits™: 1.50
ARRT Category A+ Credits: 1.50

LEARNING OBJECTIVES
1) Describe techniques for creating a spreadsheet to allow trouble-free data analysis. 2) Demonstrate key data management skills. 3) Describe tools for performing basic descriptive statistics. 4) Identify how to perform simple statistical tests and perform these tests with a sample dataset. 5) Understand how bad data (or bad data acquisition techniques) may corrupt subsequent data analyses. 6) Practice data plotting/representation techniques. 7) Identify differences between a spreadsheet and a database. 8) Identify statistical tasks that require more sophisticated software. Pre-requisites: Familiarity with Microsoft Windows and Microsoft Excel environment will be assumed

ABSTRACT
A spreadsheet program is commonly employed to collect and organize data for practicing quality improvement, for research, and for other purposes. In this refresher course, we will demonstrate to a user, familiar with Microsoft Excel environment, how this spreadsheet program may be used for such purposes. The course will begin with describing efficient approach for data acquisition and highlight key data management skills; and with reviewing commons errors that may be avoided during data logging. Then we will provide a brief introduction on basic descriptive tests before proceeding with a hands-on tutorial using a sample dataset to calculate basic descriptive statistics, and to perform basic statistical tests like t-test, chi-square test, correlation analysis, etc. Effect of corrupted data on such analysis will also be demonstrated. The final hands-on component for this course will include data plotting and representation including the use of pivot tables. The course will conclude with a discussion on identifying differences between a spreadsheet and a database, limitations of a spreadsheet program and avenues where a dedicated statistical software program would be more beneficial. A list of some of these dedicated statistical software programs for analyses will also be provided. Pre-requisites: Familiarity with Microsoft Windows and Microsoft Excel environment will be assumed
Participants

Di Zhang, Pittsburgh, PA (Abstract Co-Author) Nothing to Disclose
PURPOSE
To investigate survival outcomes in patients with stage 1a renal cell carcinoma (RCC) undergoing open or laparoscopic partial nephrectomy (PN) vs. percutaneous cryoablation (CRA) or radiofrequency ablation (RFA) in a large-scale population study.

METHOD AND MATERIALS
The most recently updated SEER-Medicare linked database was queried for patients with T1aN0M0 RCC (≤4cm, ICD-O-3 C64.9) diagnosed between 2000 and 2011 and followed to 2012. Patients who underwent therapy were selected from Medicare via CPT carrier claim codes (percutaneous RFA 50592; percutaneous CRA 50593; open PN 50240; laparoscopic PN 50543). Mean overall survival (OS) from therapy was compared between patients who underwent percutaneous ablation vs. partial nephrectomy, with subgroup survival analysis of individual therapies. Kaplan-Meier estimation and Cox proportional hazard models were used for survival analyses and to assess independent prognostic factors for OS.

RESULTS
A total of 5,983 T1a RCC patients underwent percutaneous ablation or PN within the study period, median age 72.0 yrs, 61.0% male. Of these, 3150 received open PN, 1785 received laparoscopic PN, 419 received CRA and 629 received RFA. Of these, 47.9% of patients undergoing PN were >72 yrs, vs. 67.1% of patients in the ablation group. Mean age of patients receiving ablation was significantly higher than that of the PN group, 80.1 vs. 70.6 yrs, p<0.001. Other factors including gender, ethnicity, mean index tumor size and tumor grade were not significantly different between comparison groups. Patients who underwent PN had significantly higher mean OS compared to the ablation group, 128.7 vs. 75.5 months, p<.001. On Cox regression analysis, younger age was the only independent prognostic factor for survival, HR 0.91 (0.87-0.93, p<0.001).

CONCLUSION
In T1aN0M0 RCC, patients undergoing ablation were significantly older compared to PN patients. Age was found to be an independent prognostic factor for survival from treatment.

CLINICAL RELEVANCE/APPLICATION
In T1aN0M0 RCC, age was found to be an independent prognostic factor for survival from treatment and may impact choice of therapy.

Xavier G. Azogue JR, Barcelona, Spain (Abstract Co-Author) Nothing to Disclose

PURPOSE
Evaluate the efficacy and safety of ultrasound (US) guided percutaneous radiofrequency ablation (RFA) for small renal masses. Describe the complications of RFA guided by US. Evaluate the technique in their initial ablative capacity and rate of tumor recurrence at one year minimum follow up. Illustrate postablative findings of residual or recurrent renal tumor by using Contrast-enhanced US (CEUS) Evaluate the effect of renal function in patients undergoing RFA guided by US

METHOD AND MATERIALS
Over a 7 year 105 patients with 120 renal masses (tumor size averaged 2.7 cm) were reviewed treated with US-guided percutaneous RFA. Biopsy was performed at the same moment of the procedure from 2009. Cool-tip RFA system was percutaneously inserted under ultrasound guidance. RF was emitted at 100-120 W for 12 minutes to attain temperatures sufficient to ensure tumor kill. The treatment response and technical success were defined by absence of contrast enhancement within the tumor on contrast enhanced CT and CEUS. The patients were followed up with CEUS and computed tomography at 3.6 months and every 6 months thereafter. Multivariate analysis was performed to determine variables associated with procedural outcome.

RESULTS

Follow-up ranged from 24 months to 84 months. The initial treatment success rate was 95.8%. Five of the remaining tumors were successfully re-treated. Four tumors had recurrence (defined as the occurrence of contrast enhancing tumor 12 months after complete ablation) three of whom required a second ablation and one nephrectomy. The overall technical success rate was 99%. Complications were seven self-limited included hematomas subcapsular or perirenal. In all 104 (99%) patients have preservation of renal function, only one patient developed significant renal function deterioration associated with perirenal hematoma. There were no bowel complications despite the fact that 6 of the tumors were within 1 cm of bowel. Protective strategies progressed from reliance on electrode positioning to hydro dissection.

CONCLUSION

Our experience to date suggests that US-guided RFA of small renal tumors is a safe and effective, minimally invasive technique in selected patients.

CLINICAL RELEVANCE/APPLICATION

US-guided RFA of renal tumors can provide benefits compared to other techniques: Intraprocedural monitoring affords visualization of the forming hot ball, helps detect proximity to surrounding structures and does not use ionizing radiation.

VSIO11-09 Small Renal Mass (T1a): The Case for Cryoblation

Sunday, Nov. 29 3:10PM - 3:30PM Location: S405AB

LEARNING OBJECTIVES

View learning objectives under main course title.

ABSTRACT

Cryoablation of smaller renal cancers (i.e., T1a, or <4 cm) is an out-patient treatment that is safe, effective and flexibility for nearly any renal location. Major cryoablation benefits include its excellent visualization of ablation zone extent, low procedure pain and flexible protection of tumor ablation sites near calyces, bowel and ureter. CT-guidance is the cryoablation guidance modality of choice due to circumferential visualization of low density ice and ready availability. US-guidance can augment renal cryoablation, especially for smaller visible masses and/or placement of interstitial metallic markers during biopsy for selected cases requiring better eventual CT localization. MR-guidance has little clinical benefit or cost-efficacy. For safety, cases will be considered for avoidance of direct calyceal puncture, selection of hydrodissection or balloon interposition for bowel protection, and protection of the uretero-pelvic junction by stent placement. Imaging outcomes of complications and their avoidance will be shown. For optimal efficacy, tumor size in relation to number and size of cryoprobes emphasize the “1-2 Rule” of at least 1 cryoprobe per cm of tumor diameter and no further than 1 cm from tumor margin, as well as cryoprobe spacing of <2cm. Thorough extent of visible cryoablation margins beyond all apparent tumor margins produces very low local recurrence rates for tumors in nearly any renal location, resulting in excellent cost-efficacy by minimizing the need for re-treatments.

VSIO11-10 Adjunctive Techniques to Improve Image-Guided Percutaneous Cyroablation of Renal Masses in Difficult Anatomic Locations: Quantifying Procedural Success and Long-term Outcomes

Sunday, Nov. 29 3:30PM - 3:40PM Location: S405AB

Participants
Ahmed Fadi, MD, Mineola, NY (Presenter) Nothing to Disclose
Andrew Ho, Bayside, NY (Abstract Co-Author) Nothing to Disclose
Sama Sayehgh, DO, Mineola, NY (Abstract Co-Author) Nothing to Disclose
April Griffith, Mineola, NY (Abstract Co-Author) Nothing to Disclose

Jason C. Hoffmann, MD, Mineola, NY (Abstract Co-Author) Consultant, Merit Medical Systems, Inc; Speakers Bureau, Merit Medical Systems, Inc

PURPOSE

When performing renal mass cryoablation in difficult anatomic locations, adjunctive techniques such as retrograde pyeloperfusion, hydrodissection, and angioplasty balloon interposition can improve safety and technical success rates. Prior studies have reported the technical success of these techniques, but correlation with longer-term outcomes has not been reported in this specific patient population. This study quantifies the success of these techniques, and correlates with long-term cross-sectional imaging outcomes.

METHOD AND MATERIALS

Retrospective analysis of percutaneous renal mass cryoablation was performed from September 2011 through October 2014 at a single, tertiary care institution. Cases using adjunctive techniques were analyzed. The diagnostic cross sectional imaging, procedural images and report, and follow-up multi-phasic cross-sectional imaging were reviewed by one radiology resident and one interventional radiology attending. The type of adjunctive technique used, reason for such utilization, and procedural outcome of the technique were recorded. Specifically, in cases of hydrodissection or balloon angioplasty interposition, measurements of the displacement distance were made. Minor and major complications were recorded, per Society of Interventional Radiology criteria. Longer-term outcomes were evaluated by review of follow-up cross-sectional imaging.
RESULTS
Out of 53 cryoablations during the study period, 9 utilized adjunctive techniques, including hydrodissection (n=8), retrograde pyeloperfusion (n=1), and angioplasty balloon interposition (n=1). Median greatest tumor dimension was 1.9cm (range 1.3-3.5cm). Prior to adjunctive technique, median tumor proximity to closest organ was 0.4cm (range 0.1-1.3cm). After technique was used, median distance to closest organ was 2.8cm (range 0.3-3.3cm). One hydrodissection was unsuccessful, thus angioplasty balloon interposition was then performed. All cases had appropriate ablation zones and protection of adjacent critical structures. No minor or major complications were reported. No patients had evidence of residual or recurrent tumor on follow-up imaging, ranging from 3 to 30 months.

CONCLUSION
Adjunctive techniques to allow cryoablation of renal masses in difficult anatomic locations have excellent technical success rates and long-term outcomes.

CLINICAL RELEVANCE/APPLICATION
Improving outcomes of difficult renal mass cryoablations.

VSIO11-11 Small Renal Mass (T1a): The Case for Microwave

VSIO11-12 Long-term Clinical Outcomes Following Radiofrequency and Microwave Ablation of Renal Cell Carcinoma at a Single Large VA Medical Center
Sunday, Nov. 29 4:00PM - 4:10PM Location: S405AB

Participants
Salim E. Abboud, MD, Cleveland, OH (Presenter) Nothing to Disclose
Tanay Y. Patel, MD, Cleveland, OH (Abstract Co-Author) Nothing to Disclose
Nannette Alvarado, MD, Cleveland, OH (Abstract Co-Author) Nothing to Disclose
Preeti S. Kang, MD, Pepper Pike, OH (Abstract Co-Author) Nothing to Disclose

PURPOSE
Earlier detection and a desire to preserve renal function and decrease surgical morbidity in the treatment renal cell carcinoma (RCC) has prompted increased use of percutaneous thermal ablation treatments such as radiofrequency ablation (RFA) and more recently microwave ablation (MWA). MWA has the potential to provide more complete ablation compared to RFA in part due to more uniform and higher intra-tumoral temperatures, but only a few small studies have examined the short- and long-term outcomes of MWA for RCC. This retrospective review assesses the experience and technical short- and long-term success rates of using RFA and MWA for RCC at a large VA medical center.

METHOD AND MATERIALS
Patient and tumor characteristics (tumor size, nearness to collecting system, anterior/posterior location, location relative to polar line, and endophytic/exophytic predominance) were tabulated using descriptive statistics. Group comparisons were performed by using univariate logistic regression analysis to determine factors impacting primary efficacy, secondary efficacy, and technique effectiveness. Kaplan-Meier local tumor progression-free survival following ablation was calculated.

RESULTS
71 patients with 78 renal lesions underwent ablation. Mean, primary, and secondary mean follow-up were 35.1, 33.5, and 31.3 months. Total, primary, and secondary technique effectiveness rates were 86%, 82%, and 4%, respectively. Primary efficacy and total technique effectiveness were associated with size, with p values of 0.02 and 0.001. There was no significant difference in survival curves between MWA and RFA treated patients. MWA and RFA groups were not significantly different in terms of age, BMI, or tumor size. Complications occurred in 11.5% of patients, none resulting in death. More than 90% patients were done as outpatients (sent home day of procedure) with moderate sedation. No cases used intubations or general anesthesia.

CONCLUSION
RFA and MWA both represent effective treatment modalities for RCC. Longer follow-up time and larger tumor size may be associated with the somewhat lower effectiveness rates; the comparable efficacy/complication rates compared to prior ablation studies demonstrate the feasibility of performing ablations on an outpatient basis.

CLINICAL RELEVANCE/APPLICATION
Image guided percutaneous ablation is an effective and cost-effective treatment modality for RCC in patients that are not surgical candidates.

VSIO11-13 To Biopsy or Not Biopsy the Small Renal Mass before Ablation? That Is the Question

Participants

LEARNING OBJECTIVES
View learning objectives under main course title.
ABSTRACT
Characterization of small renal masses has proven challenging. However, with appropriate CT and MR protocols, the majority of these lesions can now be characterized pre-procedurally, enabling a confident diagnosis. In this lecture, we will describe renal mass characterization protocols and describe the common imaging signatures of RCC subtypes and their common mimics including lipid poor AML and oncocytoma. This may eliminate need for preprocedural biopsy.

VSIO11-14  Biopsy or No Biopsy Before Ablation? Biopsy Every Renal Mass before Percutaneous Ablation

Sunday, Nov. 29 4:30PM - 4:50PM Location: S405AB

Participants
William W. Mayo-Smith, MD, Boston, MA (Presenter) Author with royalties, Reed Elsevier; Author with royalties, Cambridge University Press

Maurice V. Bosch, MD, PhD, Utrecht, Netherlands (Abstract Co-Author) Nothing to Disclose
Mario G Ries, PhD, Utrecht, Netherlands (Abstract Co-Author) Nothing to Disclose

PURPOSE
To investigate if MR-HIFU can provide for a reliable confluent volumetric lesion in the renal cortex in a clinically relevant time-frame in a porcine study.

METHOD AND MATERIALS
Nine anesthetized pigs were placed on a clinical Philips Sonalleve MR-HIFU therapy system integrated with a 1.5T Achieva MRI. Both acoustic energy delivery and MR-thermometry were respiratory gated and active surface cooling was employed to prevent near-field damage. A honeycomb pattern of at least seven ablation cells (9-25s, 450W acoustic power, 4x4x10 mm3 per cell) were positioned in the cortex of the kidney. The therapeutic endpoint was evaluated by a non-perfused volume (NPV) measurement using DCE-MRI. Subsequently, the animal was euthanized and the extent of induced necrosis was examined using a cellular viability staining (NADH).

RESULTS
Confluent volumes on NPV-imaging (up ~3 mL) and NADH staining (up to ~4mL) were obtained and temperatures exceeding 60°C were reached in 6 pigs. I.e. heating of the false rib, poor respiratory correction, and a large incidence angle caused poor kidney heating in 3 pigs.

CONCLUSION
These first results indicate that current clinical MR-HIFU equipment might be suitable for non-invasive therapy of renal masses. Positioning of the sonication and the subject based on anatomical scans is very important, as well as adequate motion compensation. Future work will include a first clinical study on renal cell carcinomas.

CLINICAL RELEVANCE/APPLICATION
There is an increasing interest in non-invasive kidney sparing therapy for renal cancer, since ~1.6% of men and women will be diagnosed with kidney and renal pelvis cancer during their lifetime, in 25% of all abdominal imaging sessions a renal lesion is found, partial nephrectomy - standard care for tumors <4cm - has a 15% complication rate, and the population is aging and known with comorbidities and poor physical condition. Therefore, several patient studies investigated the feasibility of HIFU for the thermal ablation of renal masses. Mainly a hand-held extracorporeal ultrasound device with US B-mode imaging for guidance or a laparoscopic approach was used. Disadvantages are i.e. the lack of respiratory motion compensation, no real-time visualization of energy deposition, and the complexity of the probe positioning. Alternatively, feasibility of MR-HIFU interventions on the kidney with respect to motion compensated real-time thermometry and acoustic energy delivery was established, recently.

Bradley J. Erickson, MD, PhD, Rochester, MN (Presenter) Stockholder, Evidentia Health, Inc; Stockholder, OneMedNet Corporation; Stockholder, VoiceIt Technologies, LLC
Harry Solomon, Barrington, IL (Presenter) Employee, General Electric Company
Brad Genereaux, Waterloo, ON, (brad.genereaux@agfa.com) (Presenter) Employee, Agfa-Gevaert Group

LEARNING OBJECTIVES
1) Understand the IHE profile for managing radiology report templates (MRRT). 2) Learn about the RSNA template library and how it works together with the MRRT profile so you can easily download and use RSNA templates. 3) Discover how the MRRT profile allows you to take your templates with you when you change systems or change jobs. 4) Review the enhanced features available in MRRT templates.

ABSTRACT
The purpose of this session is to demonstrate how existing and planned IHE profiles can help improve the workflow in a medical imaging department, and help those responsible for its operation, monitor what is happening. Prior IHE profiles focused heavily on traditional RIS and PACS. Newer projects are focused on departmental workflow management and monitoring, as well as exchange of images and reports between medical facilities. We will also describe future possible profiles for utilizing RadLex to improve radiologist efficiency and improve departmental workflow.
Pain and Sedation in 2015: Improving Quality and Patient Outcomes

Sunday, Nov. 29 2:00PM - 3:30PM Location: S504AB

Participants
Fred E. Shapiro, DO, Boston, MA (Presenter) Nothing to Disclose
Richard D. Urman, MD, MBA, Boston, MA (Presenter) Nothing to Disclose
Hesham H. Malik, MD, Worcester, MA, (Hesham.Malik@umassmemorial.org) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) An evidenced-based review of the current literature and how to measure quality and safety related to procedural sedation. 2) Understand the necessity and the role that team training contributes to a safe procedural environment. 3) Review appropriate patient selection for interventional procedures. 4) Review procedural sedation policies, accreditation, pharmacology and patient monitoring. 5) Challenging cases presentation and discussion.

ABSTRACT

The safe and effective sedation of patients during interventional Radiology procedures requires an in depth knowledge of how to administer conscious sedation. Even more important, however, is the skill set to be able to accurately assess each patient's clinical status prior to the procedure, be able to formulate a comprehensive sedation plan, and recognize which patients would be better served by involvement of an Anesthesiologist. This course will review the institutional requirements for providing minimal, moderate or deep sedation. We will also outline how to develop a procedural sedation (PS) policy, including recognition of the role that team training contributes to a safe environment. We will review the use of the Institute for Safety in Office Based Surgery (ISOBS) safety checklist as well as its customization to the IR setting. We will provide an evidenced-based review of the current literature re: QA, risk management, and process improvement using the ISOBS checklist as well as a review of drugs commonly used for procedural sedation.
MR Imaging-guided Breast Biopsy (Hands-on)

LEARNING OBJECTIVES
1) Establish criteria for MR Image-guided breast biopsy patient selection. 2) Cultivate a working understanding of MR Image-guided biopsy and needle localization instrumentation and implementation. 3) Basic MR Image-guided biopsy and needle localization parameters and requirements for appropriate coil, needle and approach selection. 4) Discuss practice integration issues. 5) Discuss pearls and pitfalls associated with successful MR Image-guided biopsy.

ABSTRACT
This course is intended to provide both basic didactic instruction and hands-on experience in the application of MRI guided breast biopsy. MRI provides greater sensitivity for detecting breast cancer compared with mammography and ultrasound, although with imperfect specificity. MRI guided biopsy is required to confirm or exclude malignancy for MRI only findings. This course will be devoted to the understanding and identification of the following pertaining to MRI guided biopsy: 1) apporpriate patient selection 2) optimal positioning for biopsy 3) target selection and confirmation 4) various biopsy technologies and techniques 5) potential problems and pitfalls.

Sub-Events

RC111A  Practical Approach for Interpreting Head and Neck PET/CT

Participants
Rathan M. Subramaniam, MD, PhD, Baltimore, MD, (rsubram4@jhmi.edu) (Presenter) Travel support, Koninklijke Philips NV

LEARNING OBJECTIVES

1) To understand the value of PET/CT in the care process of managing head and neck cancer. 2) To learn common pathways of tumor spread in head and neck. 3) To review illustrative cases and pitfalls of interpretation.

ABSTRACT

FDG-PET/CT provides valuable information in the assessment of the patient with cancers of the head and neck. The metabolic information determined by FDG is complimentary and additive to the anatomic information from CT, and can be used to direct surgery, plan radiation therapy, and evaluate response to systemic or localized treatment. In this presentation, the role of FDG-PET/CT in the management of head and neck cancer will be presented, using case examples to illustrate the utility of PET as well as common pitfalls.

**PURPOSE**

Gd contrast agent usage in placental imaging is generally contraindicated, for concerns related to fetal contrast agent exposure. We therefore developed a novel liposomal Gd nanoparticle contrast agent for T1-MRI, retaining the Gd on the maternal side, thus shielding the fetus from potential toxicities. In this study, we tested this agent in placental imaging in a mouse model, and measured its transplacental permeability.

**METHOD AND MATERIALS**

Female C57BL/6 mice, pregnant at gestational age E16.5±1 days, were imaged by T1-MRI on a 9.4T small animal MRI (Bruker Instruments) using a conventional contrast agent (Multihance, a meglumine salt of Gd-BOPTA chelate) (13 mice) and using the novel nanoparticle Gd agent (9 mice). DCE-MRI was conducted using consecutive 3D-SPGRE sequences at a constant flip angle of 16°, TE/TR=1.93ms/6ms, FOV = 3x3x2.5cm, matrix = 128x128x16. Each image was converted to a T1 map, and the contrast agent concentration on a pixel-by-pixel basis, estimated from the known relaxivity. After imaging, the mice were sacrificed and the Gd content of the placenta and fetus measured using ICP-AES.

**RESULTS**

Image and data shown below are representative of each cohort. The placentae are rather small (2mmx3mm) but are still clearly defined, and obviously not invasive into the uterine wall. Signal intensities in the placental and fetal ROIs, indicative of Gd concentration in each compartment, clearly show that the conventional Gd chelate agent penetrates the placental barrier and enters the fetus. The nanoparticle agent however, does not do so, indicated by zero signal in the fetal compartment throughout the duration of this experiment. The ICP-AES study confirmed the imaging study results, with no detectable Gd in the fetal compartment. A separate study in human placentae using an ex vivo perfused placenta preparation, also confirmed these results.

**CONCLUSION**

The nanoparticle contrast agent does not penetrate the placental barrier in a mouse model. The data are consistent with separate tests on a perfused human placenta model.

**CLINICAL RELEVANCE/APPLICATION**

The incidence of placenta accreta has increased 8-fold in the last 30 years, and improved methods for placental imaging are sorely needed. Nanoparticle Gd contrast agents described in this work could be useful for placental imaging, while maintaining fetal safety.

**RC113-03**  
**Normal and Abnormal Development of the Cerebellar Vermis - A Quantitative Fetal MRI Study**
The present work is a preliminary study on the feasibility and practical use of a Fetal MRI-US real-time fusion imaging. Thanks to

**CONCLUSION**

Pathology, fusion imaging improved the diagnosis; in the other 10 cases MRI was superior to US even using the RVS. US images. In 10 cases of body abnormalities, fusion imaging helped the diagnosis in 20%. In the 10/20 cases of encephalic the body (8 thoraco- abdominal; 2 heart). In all cases RVS was technically possible, with a 100% match between MR images and US images. Data registration, matching and comparison with standard B-Mode US and MRI images previously acquired.

**METHOD AND MATERIALS**

This study was conducted over a two-month period March-April 2015 in 30 patients referred for a morphological fetal US-based evaluation. Patients underwent Fetal MRI at 1.5 T for fetal anomalies were offered fusion imaging (Hitachi HI Vision Ascendus). The MRI image dataset acquired at the time of the examination was loaded into the fusion system and displayed together with the US image on the same monitor. Both sets of images were then manually synchronized and images were registered using multiple planes. On a total of 30 fetuses, 20 were for the encephalic district and 10 for the body (8 thoraco- abdominal; 2 heart). In all cases RVS was technically possible, with a 100% match between MR images and US images. In 10 cases of body abnormalities, fusion imaging helped the diagnosis in 20%. In the 10/20 cases of encephalic pathology, fusion imaging improved the diagnosis; in the other 10 cases MRI was superior to US even using the RVS.

**RESULTS**

In all cases RVS was technically possible, with a 100% match between MR images and US images. Data registration, matching and fusion imaging were performed in less than 15-20 minutes. On a total of 30 fetuses, 20 were for the encephalic district and 10 for the body (8 thoraco- abdominal; 2 heart). In all cases RVS was technically possible, with a 100% match between MR images and US images. In 10 cases of body abnormalities, fusion imaging helped the diagnosis in 20%. In the 10/20 cases of encephalic pathology, fusion imaging improved the diagnosis; in the other 10 cases MRI was superior to US even using the RVS.

**CONCLUSION**

The present work is a preliminary study on the feasibility and practical use of a Fetal MRI-US real-time fusion imaging. Thanks to

**METHOD AND MATERIALS**

75 fetuses (18-32 GW, mean 25.7GW) with normal brain development and 20 fetuses with different types of hindbrain malformations were scanned prenatally (1.5T, T2-TSE, voxel size 0.72/0.72/4.4mm - 1.0/1.0/4.4mm) and seven fetuses (16-30GW, mean 21.9GW, 3T, CISS sequence, resolution: 0.33/0.33/3.33mm) scanned within 24 hours postmortem were selected for postprocessing. A T2-weighted midline sagittal slice was identified and 2D vermian segmentation was performed using ITK snap (Figure).

**RESULTS**

The mean proportional size of 7/9 discriminable vermian lobules did not differ between in vivo and post mortem measurements. The relative size of the following lobules increased during gestation (Pearson, p<0.05): Culmen (r²=.460) and Declive/Folium/Tuber (r²=.439). The proportions of Lingula (r²=.564) and Proportion of Lingula (r²=.439). The Centrum (r²=.554), Proportions of Lingula (r²=.564) and Proportion of Lingula (r²=.439). The Proportion of Lingula (r²=.564) and Proportion of Lingula (r²=.439).

**CONCLUSION**

Fetal vermian lobulation can be accurately assessed by MRI between 18 and 32 GW in normal and pathological conditions. Growth of specific vermian lobules is nonuniform during the second and third trimester. Distinct patterns of vermian lobular hypoplasia can be described antenatally.

**CLINICAL RELEVANCE/APPLICATION**

Knowledge about the distinct growth patterns of specific vermian lobules is helpful in the prognostic classification of fetal hindbrain malformations.

**RC113-04 MRI-US Fusion Imaging in Real-Time Virtual Sonography for the Evaluation of Fetal Anomalies: Preliminary Stud**

**PURPOSE**

Postnatal neurodevelopmental outcome of fetuses with hindbrain malformations is dependent on normal growth and development of the cerebellar vermis. This comparative in vivo and post mortem fetal MRI study aims to quantitatively assess the relative dimensions of respective vermian lobules between 18 to 32 gestational weeks (GW) in normal and pathological conditions.

**CONCLUSION**

The present work is a preliminary study on the feasibility and practical use of a Fetal MRI-US real-time fusion imaging. Thanks to
informations from both US and MRI, fusion imaging allows better identification of the different fetal pathologies and could improve the performance of ultrasound examination.

**CLINICAL RELEVANCE/APPLICATION**

Fusion imaging is feasible for the assessment of fetal abnormalities. Because it combines information from both US and MRI techniques, fusion imaging allows better identification of the different fetal pathologies.

**RC113-05 Predictive Value of the MRI-based Ratio of Fetal Lung Volume to Fetal Body Volume in Congenital Diaphragmatic Hernia in Comparison to the MR Fetal Lung Volume and the Sonographic Lung-to-Head Ratio**

**PURPOSE**

To evaluate prognostic accuracy of the MRI-based ratio of fetal lung volume to fetal body volume (MR-FLV/ FBV) in fetuses with congenital diaphragmatic hernia (CDH) and to compare it to established prognostic parameters (the observed-to-expected MR fetal lung volume [o/e-MR-FLV] and the US-based observed-to-expected lung-to-head ratio [o/e-LHR]) with regard to survival, extracorporeal membrane oxygenation (ECMO) requirement and development of a chronic lung disease (CLD).

**METHOD AND MATERIALS**

Fetal MRI was performed in 132 patients with isolated CDH (mean gestational age 32.8±3.8 weeks) to measure FLV and FLV/FBV. Sonographic assessment of the LHR was performed within three days before or after fetal MRI. To obtain parameters that were independent from gestational age, the o/e-MR-FLV and the o/e-LHR were calculated based on normal controls, whereas calculation of the MR-FLV/FBV is independent from normal controls.

**RESULTS**

91% of the neonates survived, 37% needed ECMO therapy and 45% developed a CLD. All prenatal parameters revealed an excellent correlation with patients’ clinical outcome. MR-FLV/FBV, o/e-MR-FLV and o/e-LHR were significantly higher in survivors (p always <0.0001). Patients with ECMO requirement and patients with CLD showed a significantly lower MR-FLV/FBV, o/e-MR-FLV or o/e-LHR (p always <0.0001). Prognostic accuracy regarding survival was quite similar for the three parameters (AUC MR-FLV/FBV : 0.830, AUC o/e-MR-FLV : 0.868, AUC o/e-LHR : 0.845). Regarding ECMO requirement (AUC MR-FLV/FBV : 0.844, AUC o/e-MR-FLV : 0.843, AUC o/e-LHR : 0.736) and development of CLD (AUC MR-FLV/FBV : 0.778, AUC o/e-MR-FLV : 0.795, AUC o/e-LHR : 0.738) the MR-FLV/FBV and o/e-MR-FLV showed a slightly better prognostic accuracy compared to the o/e-LHR.

**CONCLUSION**

In CDH, assessment of pulmonary hypoplasia based on the MR-FLV/FBV, the o/e-MR-FLV or the o/e-LHR is quite similar in predicting survival. Regarding ECMO requirement and development of CLD, the o/e MR-FLV and the MR-FLV/FBV showed a slightly better prognostic accuracy compared to the US-based o/e-LHR. Compared to other prognostic parameters, MR-FLV/FBV has the advantage of being independent from the reference to a normal control group.

**CLINICAL RELEVANCE/APPLICATION**

In CDH, MRI-based MR-FLV/FBV and o/e-MR-FLV as well as US-based o/e-LHR are excellent and almost equivalent parameters to predict survival, ECMO-requirement and development of CLD.

**RC113-06 Correlation between Fetal and Postmortem Magnetic Resonance Imaging and Conventional Autopsy in the Detection of Fetal Abnormalities**

Sunday, Nov. 29 3:00PM - 3:10PM Location: S102AB

Participants
Matteo Saldari, MD, PhD, Rome, Italy (Presenter) Nothing to Disclose
Silvia Bernardo, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Carlo Catalano, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Valeria Vinci, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose
Lucia Manganaro, MD, Rome, Italy (Abstract Co-Author) Nothing to Disclose

**PURPOSE**

To compare fetal and postmortem MRI and conventional autopic findings in cases of major pathological abnormalities.

**METHOD AND MATERIALS**

In this prospective study we enrolled 128 fetuses with identified US findings of severe fetal malformations, with local research ethics committee approval. Among these, we performed 94 whole body Fetal MRI on 94 fetuses using a 1.5 T MR scanner and of these, only 89 women underwent termination of pregnancy because of the fetal abnormalities. Of the 89 patients, 80 (90%) consented to postmortem MRI alone; 59 (66%) women consented to both postmortem MRI and conventional autopsy and formed our study group. Following delivery, fetuses were stored in refrigerated compartments prior to MR imaging and autopsy. Also for the post-mortem imaging evaluation we acquired whole body MR imaging using a 1.5 T MR scanner. MR images were reviewed by a team of two radiologists blinded to the autopic data. Pathologists who performed conventional autopic were blinded to the MR data; autopic data were considered the gold standard.
RESULTS
Final autopic diagnoses were: polycystic kidney disease (n=15), diaphragmatic hernia (n=10), lissencephaly (n=4), type-2 Arnold-Chiari malformation (n=6), Dandy-Walker syndrome (n=13), cloacal malformation (n=1), anencephaly (n=1), holoprosencephaly (n=4), rhombencephalosynapsis (n=2), Walker-Warburg syndrome (n=2), schizencephaly (n=1). MRI-autopsy provided additional information in 10/59 (17%) compared to fetal MRI. In 6 cases (10%) conventional autopsy provided superior diagnostic information compared to MRI-autopsy. On the other hand, in 7 cases (12%) the disruption of the anatomy during autopic dissection of the fetal body couldn't allow a correct identification of the pathology.

CONCLUSION
MR autopsy is accepted by nearly all mothers while conventional autopsy is accepted by about two-thirds of mothers, it provides similar information compared to conventional autopsy in case of fetal malformations and it allows the evaluation of the pathology in case of tissue disruption during the autopic evaluation.

CLINICAL RELEVANCE/APPLICATION
Fetal MRI can add significant additional information and may be use to guide conventional autopsy

RC113-07 Imaging of Ambiguous Genitalia

Participants
Jeanne S. Chow, MD, Boston, MA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) The purpose of this course is to understand the important role of the radiologists in infants with ambiguous genitalia. Imaging techniques as well as important imaging findings will be detailed.

ABSTRACT
Participants

Sub-Events

RC112A  TEVAR Indications and Outcomes

Participants
Michael D. Dake, MD, Stanford, CA (Presenter) Scientific Advisory Board, W. L. Gore & Associates; Scientific Advisory Board, Abbott Laboratories; Research Consultant, Cook Group Incorporated; Research Consultant, TriVascular, Inc; Research Consultant, Medtronic, Inc; Research Consultant, Intact Vascular, Inc; Research Consultant, Novate Medical; Research support, Cook Group Incorporated; Research support, Medtronic, Inc; Research support, W. L. Gore & Associates, Inc.

LEARNING OBJECTIVES
1) Understand the current applications of thoracic endografts for management of thoracic aortic pathologies. 2) Recognize the benefits and existing limitations of current endograft technologies for treatment of different aortic lesions. 3) Identify the complications and failure modes of TEVAR. 4) Know the current outcome metrics typically evaluated after TEVAR treatment of thoracic aneurysms and aortic dissections. 5) List the important imaging findings and criteria currently used to assess the suitability of aortic anatomy for TEVAR.

RC112B  New Endografts for Complex AAA

Participants
Constantino S. Pena, MD, Miami, FL (Presenter) Speakers Bureau, Cook Group Incorporated; Advisory Board, C. R. Bard, Inc; Advisory Board, Boston Scientific Corporation; Advisory Board, General Electric Company;

LEARNING OBJECTIVES
1) Discuss the status of established AAA endografts. 2) Discuss new endografts for the treatment of AAA. Particularly discuss areas of improvement over established endografts. 3) Present data on novel endografts being developed.

RC112C  Old Endografts with New Complications

Participants
Elliot K. Fishman, MD, Owings Mills, MD (Presenter) Research support, Siemens AG Advisory Board, Siemens AG Research support, General Electric Company Advisory Board, General Electric Company Co-founder, HipGraphics, Inc

LEARNING OBJECTIVES
1) Understand the spectrum of complications which may be seen in patients with endografts that have been in place for several years and the significance of these complications. 2) Develop a strategy for the evaluation of endovascular stents with specific scanning protocols and the role of post processing of the data into 3D. 3) understand the complexities of complications including involvement of bowel and adjacent organs and the CT findings that can suggest these complications.

**RC120A**  
**Fundamentals in Radiation Oncology Imaging of Head and Neck Cancer**

Participants  
Hilda E. Stambuk, MD, New York, NY  
(Subtitle) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Define key anatomy and understand pathways of tumor spread for head and neck cancers. 2) Identify radiographic features of the patterns of tumor involvement. 3) Understand the implications of radiographic imaging in treatment planning.

**ABSTRACT**

Radiographic imaging is integral to diagnosis, extent of disease assessment, treatment planning and post-treatment surveillance in patients with head and neck cancer. Since the overwhelming majority of cancers of the head and neck are squamous cell carcinoma, these tumors will be the primary focus of the lecture. In addition, choosing the appropriate imaging modality is of vital importance in effective evaluation and therefore the pros and cons of imaging modalities in particular subsites will be presented. The patterns of tumor spread depend on the site of origin of the tumor and will be discussed in detail for some of the common sites such as nasopharynx and oropharynx that are treated primarily with radiation. The implications of pathways of tumor involvement including perineural spread on treatment planning will be emphasized. This lecture will provide radiation oncologists a basic understanding of the role of imaging and will highlight pearls and pitfalls that can influence management.

**RC120B**  
**Fundamentals in Radiation Oncology Imaging of Thoracic Malignancies**

Participants  
David Palma, MD, FRCPC, London, ON  
(Subtitle) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To review the normal imaging changes after precision radiotherapy for lung cancer. 2) To discuss methods of distinguishing recurrence vs. fibrosis after stereotactic radiotherapy. 3) To highlight difficult imaging cases in assessing response after radiotherapy.

**ABSTRACT**

**RC120C**  
**Fundamentals in Radiation Oncology Imaging of Skull Base Tumors**

Participants  
Jason Rockhill, MD, Seattle, WA  
(Subtitle) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Identifying imaging techniques to help delineate target volumes for skull based tumors. 2) Discuss the challenges of determining target volumes for skull based tumors in the resected and non-resected patient. 3) Review key features to follow by imaging of skull based tumors after radiation therapy.

**RC120D**  
**Imaging and RT QA in Cancer Clinical Trials: The Advanced Technology Consortium (ATC), the Quality Assurance Review Center (QARC), and the Imaging and Radiation Oncology Core (IROC)**

Participants  
Thomas J. Fitzgerald, MD, Worcester, MA

RC117A Neurologic Applications of MR-guided HIFU

Participants
Max Wintermark, MD, Lausanne, Switzerland, (max.wintermark@gmail.com) (Presenter) GE NFL advisory board;

LEARNING OBJECTIVES
1) To understand the neuro applications of HIFU. 2) To understand the challenges of applying HIFU for neuro applications. 3) To review the ongoing trials of neuro applications of HIFU.

ABSTRACT
MR guided focused ultrasound is a new, minimally invasive method of targeted tissue thermal ablation that may be of use to treat central neuropathic pain, essential tremor, Parkinson tremor, and brain tumors. The system has also been used to temporarily disrupt the blood-brain barrier to allow targeted drug delivery to brain tumors. We will discuss current and potential neuro applications of this exciting technology.

RC117B Gynecologic Applications of MR-guided HIFU

Participants
Young-Sun Kim, MD, Seoul, Korea, Republic Of (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Explain pros and cons of MR-guided HIFU in the treatment of uterine fibroids and adenomyosis as compared to other therapeutic modalities 2) Assess important factors in screening MR exams of MR-guided HIFU therapy of uterine fibroids 3) Explain treatment strategy of MR-guided HIFU therapy of uterine fibroids to improve therapeutic outcomes 4) Describe the current limitations of MR-guided HIFU of uterine fibroids and explain how to overcome limitations

ABSTRACT
Uterine fibroid and adenomyosis are the most popular clinical applications of MR-guided HIFU (high-intensity focused ultrasound) therapy. As a totally non-invasive interventional therapeutic modality using small foci of hyperthermia, MR-guided HIFU has pros and cons as compared to other therapeutic modalities. However, owing to its greatest merit of complete non-invasiveness, its clinical adoptions are increasing worldwide. MR-guided HIFU therapy has certain inborn limitations, therefore, appropriate screening in MR-guided HIFU of uterine fibroids is extremely important to improve overall therapeutic outcomes. In order to do so, properties of the target fibroids, safe pathway of sonications, complication-related factors should be well analyzed in screening MR exams. Furthermore, the symptom-relevant fibroid or the portion of fibroid should be recognized and completely ablated. As accumulations of clinical experiences of MR-guided HIFU therapy, there have been several techniques or strategies developed to overcome such limitation or to improve therapeutic efficacy, which will be covered in this presentation.

RC117C Body Applications of MR-guided HIFU

Participants
Alessandro Napoli, MD, Rome, Italy (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To become familiar with the basic physical principles of HIFU and the potential of MR guidance. 2) To approach selection criteria in MRI screening examinations for accurate indications and identify contraindications and non-suitable patients. 3) To appreciate current results and potential therapy regimens. 4) To understand recent technical developments and their potential.

ABSTRACT
The concept of ideal tumor surgery is to remove the neoplastic tissue without damaging adjacent normal structures. High-intensity focused ultrasound (HIFU) was developed in the 1940s as a viable thermal tissue ablation approach. In clinical practice, HIFU has been applied to treat a variety of solid benign and malignant lesions, including pancreas, liver, prostate, and breast cancers, soft tissue sarcomas, and uterine fibroids. More recently, magnetic resonance guidance has been applied for treatment monitoring during focused ultrasound procedures (magnetic resonance-guided focused ultrasound, MRgFUS). Intraoperative magnetic resonance imaging provides the best possible tumor extension and dynamic control of energy deposition using real-time magnetic resonance imaging thermometry. The fundamental principles and clinical indications of the MRgFUS technique will be introduced; different treatment options and personal outcomes will be discussed.

RC117D Palliation of Painful Metastases to Bone
LEARNING OBJECTIVES

1) Therapeutic options for palliation of painful metastases to bone. 2) Patient selection for MR guided focused ultrasound palliation of painful bone metastases. 3) Results of Phase III pivotal study of ExAblate MR guided focused ultrasound for palliation of painful bone metastases. 4) Technical aspects of successful patient treatment. 5) Immediate post-treatment imaging-based assessment of results. 6) Future applications of MR guided focused ultrasound for the management of osseous metastatic disease.

ABSTRACT

Cancer patients commonly have metastases to bone; as the survival of cancer patients is prolonged by more effective therapies, the prevalence of patients with metastases to bone is also increasing. Bone metastases are often painful, and often diminish the quality of life. Radiation therapy (RT) is the standard of care for the treatment of bone metastases, but a significant subset of patients do not respond to RT. MR guided focused ultrasound non-invasively achieves localized tissue ablation and provides a proven method of pain relief in patients who do not respond to radiation therapy. MR imaging provides a combination of tumor targeting, real-time monitoring during treatment, and immediate verification of successful treatment. The results of the pivotal Phase III trial that led to FDA approval of the ExAblate MR guided focused ultrasound device for the palliation of painful metastases to bone will be reviewed. In particular, patient selection, the technical aspects of successful patient treatment, and post-treatment assessment of results will be described. Concepts for future development of this technology with regard to the management of osseous metastatic disease will also be presented.
Creating and Delivering Online and Mobile Education Content: From Online Courses to Interactive iBooks (Hands-on)

Sunday, Nov. 29 2:00PM - 3:30PM Location: S401CD

Participants
George L. Shih, MD, MS, New York, NY, (george@cornellradiology.org) (Moderator) Consultant, Image Safely, Inc; Stockholder, Image Safely, Inc; Consultant, Angular Health, Inc; Stockholder, Angular Health, Inc;

LEARNING OBJECTIVES
1) Assess the potential of online and mobile e-learning innovations to augment your residents', medical students', and staff's educational curricula. 2) Acquire the domain knowledge to use already available content (e.g., PowerPoint presentations) to both create video content and deploy e-learning courses on modern web-based and mobile platforms. 3) Acquire the domain knowledge to create an interactive Apple iBook (electronic books) with text, images, video, and interactive questions.

ABSTRACT
1. From OpenCourseWare to the Khan Academy, and now to Coursera and edX, e-learning has been dramatically improved over the last decade, changing education from the normal classroom into learning done at convenience, and also allows for more creative and engaging content during the typical lecture. Stanford Med published positive initial findings in utilizing video-based lectures in an interactive class setting. Leveraging this new way of learning, requires knowledge about the types of technology and platforms for these courses. The workflow required to host an e-learning course can be summarized in 3 steps: (a) creating the educational content, (b) hosting the materials, and (c) making the materials available to the intended audience. E-content today typically consists of lecture slides along with video recordings captured by technology like TechSmith Camtasia (non-free) and Apple Quicktime (free). Once the materials are created and edited, one must choose a suitable hosting platform realistic to the skills and goals of the instructor with options that include coursesites.com, iTunes U, and YouTube / Google Hangouts. Students can then be invited to view the material or the content can be made available to the public. 3. Creating and publishing e-books is a great way to share your teaching material as an engaging interactive tool. Publishing in e-book format solves many logistical problems of conventional publishing and the e-book format has interactive features that paper books can't match. We will review the process of creating your own e-book from assembling material to layout design to submitting for e-publication. Specifically Apple iBooks Author software will be used to demonstrate converting an existing Powerpoint presentation or journal publication into an e-book. In addition, the course will go over how to publish with or without DRM (copy-protection) and ways to obtain an ISBN for publishing for sale. Online resources will also be reviewed.

Aliya Qayyum, MBBS, Houston, TX (Presenter) Nothing to Disclose
Richard M. Gore, MD, Evanston, IL (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Describe MRI; MRCP techniques for evaluating biliary disease. 2) List applications in malignant biliary disease. 3) List applications in benign conditions of the biliary tract.

ABSTRACT
This workshop is designed to review the broad spectrum of morphologic and functional features encountered in patients with cholestatic liver diseases involving the intrahepatic and extrahepatic bile ducts and adjacent liver parenchyma, in correlation with the histopathologic hallmark of this group of diseases the so-called "vanishing duct sign. We will start by explaining the role of various different imaging modalities including invasive endoscopic retrograde cholangiopancreatography (ERCP) and non-invasive conventional T2 weighted magnetic resonance cholangiography (MRCP) as well as gadoxetic acid-enhanced T1 MRCP and diffusion weighted images to expedite the evaluation of patients with known or suspected cholestatic liver diseases. Next, we will discuss the broad spectrum of biliary disorders that define cholestatic liver diseases including: primary sclerosing cholangitis (PSC), primary biliary cirrhosis (PBC), ischemic cholangiopathy, chronic rejection following liver transplant, drug-induced liver injury (DILI), infectious secondary cholangitis, cystic fibrosis (CF), etc.

RC153A  ACR RadPeer Experiences

Participants
Robert S. Pyatt, MD, Chambersburg, PA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Discuss the components of the ACR RADPEER system. 2) List the strengths and weakness of RADPEER.

ABSTRACT

RADPEER is the ACR peer review system, used by over 17,000 radiologists. It is the largest radiology peer review system in the world. RADPEER has undergone many improvements since first released, and more improvements are coming in the future. RADPEER design includes an interesting case section. Future improvements may be in ways to use RADPEER data for Performance Improvement activities.

RC153B  Focus on Workflow Integration

Participants
Tarik K. Alkasab, MD, PhD, Boston, MA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe how RADPEER-based systems are typically integrated into radiology workflows. 2) Describe how alternative, group-based peer review systems can be integrated into radiology workflows. 3) Discuss emerging methods of integrating radiology peer review with the radiologist workday.

RC153C  Peer Review Analytics

Participants
V. Anik Sahni, MD, Boston, MA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the importance of analytics in the peer review process. 2) Explore the IT solutions available to develop an analytics tool. 3) Discuss data presentation and important key metrics.

RC153D  Impact of Peer Review on the Quality of Interpretation

Participants
Jonathan B. Kruskal, MD, PhD, Boston, MA (Presenter) Author, UpToDate, Inc

LEARNING OBJECTIVES

1) Discuss emerging options for effective peer review. 2) Describe ways in which peer review can result in improved performance. 3) Describe methods for improving the utility and effectiveness of the peer review process.

RC115A  ACR Accreditation

Participants
Brett T. Parkinson, MD, Salt Lake Cty, UT (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand the history and current relevance of Breast Imaging Accreditation. 2) Be familiar with the scoring standards for breast imaging accreditation, including reasons for failure. 3) Learn about electronic submission of mammography images for accreditation. 4) Appreciate the importance of attaining Breast Imaging Centers of Excellence status.

RC115B  Mammography: A Practical Approach to Breast Lesions

Participants
Gilda Cardenosa, MD, Richmond, VA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) The participants should be able to develop a practical common sense approach to the detection and subsequent evaluation of breast lesions. The participant should be able develop an approach focused on the use of prior films, additional spot compression views and ultrasound in establishing the significance of screen detected lesions and the evaluation of patients presenting with clinical signs and symptoms.

ABSTRACT

A basic, practical and common sense approach in the detection and evaluation of potential breast lesions is presented. As a starting point the need to sit back and review the images globally for potential technical issues that may limit or preclude interpretation, breast size asymmetry, parenchymal asymmetry (focal, global or developing) and the presence of diffuse changes will be discussed. After the images are accessed globally, the active search for the presence of potential masses, calcifications and distortion will be discussed. The importance of using prior films, additional spot compression views, physical examination and ultrasound before making management decisions will be emphasized all towards the goal of minimizing potential delays in the diagnosis of early breast cancers.

RC115C  Breast Ultrasound

Participants
Paula B. Gordon, MD, Vancouver, BC (Presenter) Stockholder, OncoGenex Pharmaceuticals, Inc; Scientific Advisory Board, Hologic, Inc; Scientific Advisory Board, RealImaging

LEARNING OBJECTIVES

1) Participants should have greater confidence in performing and interpreting breast ultrasound exams, with an understanding of knobology and post-processing to produce optimal images, and to make use of Doppler to assess breast masses. A brief explanation of elastography will be included. 2) Participants will also gain understanding of the challenges of mammographic-sonographic correlation, and an approach for when correlation is uncertain.

ABSTRACT

Breast ultrasound is an indispensable adjunct to mammography. Using BIRADS criteria, ultrasound can provide critical information that can lead to the earlier diagnosis of cancer, but also allow a definitive benign diagnosis and eliminate the need for invasive procedures. This requires optimal imaging. This course will cover the fundamentals of breast ultrasound including: Equipment selection, set-up and optimization, including the proper use of focal zones, compounding and harmonics, Doppler and elastography. Lesion characterization using BIRADS descriptors will be discussed for simple and complicated cysts, and criteria for distinguishing benign from malignant solid masses. Mamographic/sonographic correlation is key, when the indication for the examination is investigation of a mass seen at screening mammography. This is fairly straightforward when the mass is large and solitary, but more challenging when it is small and/or there are multiple masses. The ultrasound finding has to correspond to the location of the mammographic mass as well as the character of the mass.
**ABSTRACT**

Biomarkers have been embraced by both the scientific and regulatory communities as surrogates end points for clinical trials, paving the way for their widespread use in medicine. The field of imaging biomarkers has exploded, and the their integration into clinical practice relies on finding and intersecting with the field of bioinformatics. Once specific biomarkers are shown to have value, easily integrating them into the digital environment of the radiologist and communicating them to the healthcare providers and on directly to patients efficiently and seamlessly is important for their value and impact on health to be realized. Culturally, it is taking radiologists from the era of description and largely qualitative reporting, into a quantitative future state, and leveraging informatics to extract information from imaging alone or together with data available in the electronic medical record is essential for future success in this new world. To get there, understanding the impact of this approach as a value of our services, and standardizing of imaging techniques along the lines of what the RSNA QIBA initiative is designing, are essential, so that biomarkers are robust, accurate and reprodicbile. Embracing this approach enables and facilitates new approaches, relationships of imaging and IT researchers, vendors and consumers, to fully realize the possibilities. This course will discuss and describe the overall constructs, and use tangible exams of using this in practice today and for the future.

**LEARNING OBJECTIVES**

1) To learn what the term precision medicine means. 2) To understand how informatics intersects with clinical radiology to enable precision medicine in practice. 3) To learn through concrete examples how informatics based radiology precision medicine impacts health

The purpose of this presentation is to describe how the screening, diagnosis, and treatment of lung nodules can be personalized utilizing data from the NLST and PLCO clinical trials and how the Fleischner Guidelines and screening criteria for lung cancer can be modified according to the characteristics of an individual patient and individual nodule. The presentation will also include ways in which a facility can collect local data on their own patients to supplement these reference databases with experience from their own patient population.

**Learning Objectives**

1) Describe how data from a clinical trial can be repurposed as a decision support tool. 2) List some of the potential techniques that can be utilized to predict likelihood of a malignant nodule from the NLST database. 3) Explain how the Fleischner Guidelines can be personalized utilizing data from NLST and PLCO. 4) Detail the implications for lung screening trials of having access to NLST and PLCO data. 5) Demonstrate how a healthcare enterprise can create their own local reference database using information from their own patient population.

**ABSTRACT**

The era of personalized/precision medicine offers the potential to utilize patient and lesion specific data to personalize screening and diagnostic work-up, diagnosis, and treatment selection to a particular patient to optimize effectiveness. Although recently, the emphasis has been on utilization of genomic data in personalized medicine, there is a 'gold mine' of useful data in previously conducted clinical trials as well as patient medical electronic records that has, until now, gone largely untapped. The purpose of this presentation is to describe how the screening, diagnosis, and treatment of lung nodules can be personalized utilizing data from the NLST and PLCO clinical trials and how the Fleischner Guidelines and screening criteria for lung cancer can be modified according to the characteristics of an individual patient and individual nodule. The presentation will also include ways in which a facility can collect local data on their own patients to supplement these reference databases with experience from their own patient population.
LEARNING OBJECTIVES

View learning objectives under main course title.

ABSTRACT

Cardiovascular diseases (CVD) develop over an individual’s lifetime. CVD is the number one cause of death and morbidity worldwide. Integrated application of genomics, quantitative imaging and "big data" has the potential to positively transform cardiovascular prevention and care and reduce the health and economic consequence of CVD. In this talk we will review how easily obtainable imaging biomarkers, already available, can power this change. Measures of cardiac and vascular structure and function as well as body composition provide great insight into and individual’s risk of CVD, level of physical activity, diet, vascular health and general well-being.

RC105A Pituitary Lesions: Not as Easy as They Seem

Participants
Michael N. Brant-Zawadzki, MD, Newport Beach, CA, (mbrant@hoag.org) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Appreciate the prevalence of "incidental" lesions within the pituitary gland, and their origin. 2) Differentiate intrinsic pituitary gland lesions from non-pituitary lesions simulating intrinsic disease. 3) Utilize common MRI parameter choices to help specify pathology in the pituitary region.

ABSTRACT
The pituitary gland's size, important function, and detailed surrounding anatomy of disparate structures makes it an "acid test" for the accuracy and specificity of any imaging modality. The multiplicity of intrinsic lesions, as well as the plethora of surrounding structural histology produces a wide bandwidth of abnormalities in the pituitary fossa and its environs. A systematic approach to analyzing lesions of the pituitary region will be presented, common pitfalls explored, and atypical examples utilized to review the approach to a targeted differential diagnosis for lesions of this region.

RC105B Is it Vasculitis?

Participants
Daniel M. Mandell, MD, Toronto, ON, (danny.mandell@uhn.ca) (Presenter) Research funded, General Electric Company;

LEARNING OBJECTIVES
1) Appreciate the spectrum of imaging findings in CNS vasculitis. 2) Appreciate findings that help differentiate among related conditions. 3) Understand the role of imaging relative to other tests (CSF sampling, biopsy etc...).

ABSTRACT
Abstract: Central nervous system (CNS) vasculitis is relatively uncommon. However, multifocal abnormalities on CT/MRI and/or intracranial arterial narrowing on CTA/MRA often leads to consideration of this diagnosis. I will discuss the spectrum of imaging findings in CNS vasculitis, including brain parenchymal and meningeal findings, angiographic findings, and the emerging role of vessel wall MRI. I will then focus on the differential diagnosis, and findings that can help differentiate among conditions that mimic vasculitis. Finally, we will consider how imaging fits into the broader clinical work-up which may include cerebrospinal fluid sampling and biopsy.

RC105C Spontaneous Intracranial Hypotension

Participants
William P. Dillon, MD, San Francisco, CA, (william.dillon@ucsf.edu) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Understand the clinical presentation, variations thereof, and MR and CT feature of SIH. 2) Understand the approach to treatment of SIH with autologous blood patch. 3) Understand the potential complications of SIH, and blood patch.

ABSTRACT
Spontaneous intracranial hypotension (SIH) is a syndrome of low cerebrospinal fluid volume and or pressure that typically results from either a spinal dural defect at a perineural cyst or from an osteophyte/disc penetrating through the ventral dura. Postural headache is the most common symptom. Other reported symptoms include nausea, vertigo, cranial nerve palsies, visual impairment, quadriplegia, and coma. Because of the nonspecific nature of symptoms, the diagnosis may be missed or mistaken for other disease entities. These patients may be surgically treated for subdural fluid collections or 'Chiari 1 malformations' instead of the underlying spinal cause of intracranial hypotension. Patients with connective tissue disorders - such as Marfan syndrome, Ehlers-Danlos syndrome, and autosomal dominant polycystic kidney disease - are at increased risk of SIH. The most appropriate therapy for SIH is an epidural blood patch, which ideally should be directed to the location of the leak, if it is known. If the location of the leak is unknown, then the epidural blood patch can be placed in a nonselective fashion. Described imaging findings of SIH include diffuse pachymeningeal enhancement, subdural fluid collections, cerebellar tonsillar herniation, distention of the dural venous sinuses, enlargement of the pituitary gland and downsloping of the floor of the third ventricle. Ct guided epidural blood patch following detection of the CSF fistula is the most efficient and appropriate first line of therapy. The diagnostic findings, complications of
untreated SIH, and the approach to the patient with suspected CSF fistula of the spine will be discussed.
Quantitative Imaging Mini-Course: Promise and Challenges

Sunday, Nov. 29 2:00PM - 3:30PM Location: S502AB

RC125A The Perspective of the RSNA Quantitative Imaging Biomarker Alliance (QIBA)

Participants
Edward F. Jackson, PhD, Madison, WI, (efjackson@wisc.edu) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Describe the need for and benefits of implementing quantitative image analyses in clinical trials and clinical radiology practice. 2) Understand the activities that RSNA supports to help move the profession of radiology from a primarily qualitative interpretation paradigm to a more quantitative-based interpretation model. 3) Describe the challenges of extracting uniform, standardized quantitative measures from clinical imaging scans. 4) Provide examples of approaches to resolving some of these challenges.

ABSTRACT
The RSNA Strategic Plan strives to advance the radiological sciences and foster the development of new technologies in part by promoting the quantification of imaging results. The added value of quantification in both research and clinical environments is likely to increase as health care initiatives place increased pressure on radiologists to provide decision support for evidence-based care. There remain substantial barriers to the widespread use of quantitative measures in clinical radiology, including an inherently large number of variables that impede validation of specific metrics, diversity of proprietary industry platforms, and lack of acceptance by radiologists. A critical barrier to the implementation of quantitative imaging in radiology is the lack of standardization among vendor platforms. Collaboration in the pre-competitive space is challenging yet crucial to address standardization, and integrating quantitative measurement into workflow will be necessary for wide adoption. The Quantitative Imaging Biomarkers Alliance (QIBA) was officially launched in 2007 as a means to unite researchers, healthcare professionals, and industry stakeholders in the advancement of quantitative imaging. QIBA's mission is to improve the value and practicality of quantitative biomarkers by reducing variability across devices, patients, and time. The four QIBA modality-driven Coordinating Committees (CT, MR, Nuclear Medicine, US) currently oversee nine Biomarker Committees, and associated task forces, that develop QIBA Profiles (i.e., documents) of standardized technical performance specifications for image acquisition, data processing and analysis, and compliance.

RC125B NCI’s Quantitative Imaging Network (QIN) Perspective

Participants
Robert J. Nordstrom, PhD, Rockville, MD (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Gain an overview of the NCI Quantitative Imaging Network (QIN). 2) Identify conditions for application submission and review. 3) Identify the needs and benefits for implementing quantitative imaging principles aimed at measurement or prediction of response to therapy in clinical trials. 4) Understand the need for network involvement in these activities.

ABSTRACT
The NCI Quantitative Imaging Network (QIN) is an international association of research teams with the mission to improve the role of quantitative imaging for clinical decision making in oncology by the development and validation of data acquisition, analysis methods, and tools to tailor treatment to individual patients and to predict or monitor the response to drug or radiation therapy. To that end, the teams are moving from the activities of developing and optimizing decision support tools to validating them in clinical environments. This lecture will chart the history of the QIN, show examples of the research results from several teams, and review results of the recent annual meeting.

RC125C Clinical Trial Perspective

Participants
Lawrence H. Schwartz, MD, New York, NY (Presenter) Committee member, Celgene Corporation; Committee member, Novartis AG; Committee member, ICON plc; Committee member, BioClinica, Inc

LEARNING OBJECTIVES
1) Gain an overview of the NCI’s National Clinical Trials Network (NCTN). 2) Identify the need for Quantitative Imaging within the trial network and in specific trials. 3) Review examples of trial design incorporating Quantitative Imaging. 4) Review recent initiatives in Precision Medicine and the potential role for Quantitative Imaging.

ABSTRACT
Advances in the understanding of the cancer genome has supported the development of targeted therapeutics such as imatinib, erlotinib, crizotinib, and vemurafenib that have changed the approach to cancer treatment, allowing for individualized therapy. In order to study these targeted therapies in an individual manner, cancer clinical trials will need to screen large numbers of patients...
in order to identify the subset with the molecular targets that are appropriate to study. In addition, improved efficiencies have been implemented to streamline important central functions related to tissue banks, regulatory approvals and imaging transfer and archiving. The role of imaging both within the NCTN and in precision medicine is undergoing change as well. This will be explored and discussed to understand how we can optimize the role of Quantitative Imaging.
**RC108A  Imaging of Drug Smuggling**

Participants
Ferco H. Berger, MD, Amsterdam, Netherlands, (f.berger@vumc.nl) **(Presenter)** Nothing to Disclose

**LEARNING OBJECTIVES**
1) Comprehend the socio-economic background of drugs and the different ways of intra-corporeal transportation and packing materials used. 2) Analyze the different imaging techniques for detection of illicit drugs trafficking, detect the findings and know the potential lack thereof. 3) Comprehend with the complications that can occur and the imaging findings thereof.

**ABSTRACT**
The drugs industry is reported to make up to almost 1% of global GDP and 1/3 of the population has tried illicit drugs in their life. Overdosing causes a staggering estimated 1 death per hour in Europe alone. Trafficking of drugs occurs by ingestion (body packers) or vaginal/rectal insertion (body pushers). As can be imagined, ingestion / insertion of packets of drugs can cause different kinds of clinical problems, depending on packaging material and type of drug. Detection of packets by screening methods as well as acute and subacute clinical conditions and the depiction thereof by different imaging modalities will be discussed. The participants of this RC will get to know the current developments in both the packets as well as the imaging of their features and complications.

**RC108B  The Virtual Autopsy—Bridging Radiology and Forensics**

Participants
Michael J. Thali, MD, Zurich, Switzerland, (thali@irm.uzh.ch) **(Presenter)** Nothing to Disclose

**LEARNING OBJECTIVES**
1) To Improve basic knowledge and skills of forensic imaging for radiologists. 2) To give an update of the historical and current development and techniques in forensic imaging in the world. 3) To present the newest research areas in forensic imaging and radiology. 4) To discuss workflow and present possibilities and options. 5) To show how to get involved in forensic imaging / radiology.

**ABSTRACT**
The modern virtual autopsy approach (called Virtopsy) began at the turn of the millennium as multi-disciplinary applied research project to implement imaging modalities from diagnostic radiology and surveying technology in forensic sciences. Since then, the Virtopsy approach has become a standard procedure in forensic investigations. Today, computed tomography, magnetic resonance imaging, optical 3D surface scanning, and 3D photogrammetry are routinely used to detect and document forensic evidence in a minimally-invasive and observer-independent manner in both the living and the deceased. Virtopsy can enhance traditional autopsy or even replace it in selected cases. One of the main benefits of imaging lies in the observer-independent documentation of forensically relevant findings. In addition, digital imaging data can be stored permanently and may be re-examined at any time if a second opinion is required. In living patients, Virtopsy permits the documentation of patterned injuries such as bite marks, bruises, lacerations, and abrasions. Documentation is made in three dimensions, true to scale, and enables comparison of injuries to potential injury causing instruments. Virtopsy provides in the court excellent tools for crime and accident reconstruction, including 3D depictions of internal injuries, 3D true color representations of surface injuries and even 3D scaled models of entire crime scenes and events. The Virtopsy approach reproduces critical forensic evidence in an unbiased and comprehensible fashion, suitable for presentation as evidence to laypersons and legal professionals.

**RC108C  Medical Effects of Nuclear Weapons**

Participants
Bruce R. Javors, MD, New York, NY, (bjxraydoc@gmail.com) **(Presenter)** Nothing to Disclose

**LEARNING OBJECTIVES**
1) Compare conventional and nuclear weapons and explain their fundamental differences. 2) Comprehend the various short term effects including thermal, blast and radiation injuries. 3) Identify and understand the long term consequences of nuclear blasts
especially those from radiation exposure. 4) Understand the societal disruption that may follow the use of nuclear weapons.

**ABSTRACT**

Since 1945 society has been faced with both the possible and real aftetmaths of nuclear weapons and their use. Nuclear weapons are both quantitatively and qualitatively different from chemical explosives. Those differences will be briefly presented. Immediately after detonation, most of the energy released by a weapon is in the form of blast and heat with only a small amount of radiation produced. The formers' effects on most organ systems will be reviewed along with acute radiation sickness and the resultant difficulties of shielding oneself from those effects. The delayed results of radiation exposure will also be discussed. Included are carcinogenesis and mutagenesis. Possible ecologic and social disruption will be presented. Focus will also be placed on infectious diseases especially in light of both the diminished host and organized medical responsiveness. The myths and realities of terrorist devices, so-called suitcase bombs, will be reviewed. Appropriate video and still photographs will accompany many of the above items.
The Aging Radiologist: How to Cope, When to Quit (Sponsored by the RSNA Professionalism Committee) (An Interactive Session)

Sunday, Nov. 29 2:00PM - 3:30PM Location: S402AB

Participants
Donald M. Bachman, MD, Framingham, MA (Moderator) Nothing to Disclose

LEARNING OBJECTIVES
1) Identify physiological and psychological manifestation of aging specific to performance as a radiologist. 2) Institute non-prejudicial evaluation of function and performance of radiologists in their department as they age. 3) Understand economic, health, emotional and professional factors that stimulate radiologists to either continue working or retire. 4) Identify strategies for instituting meaningful and satisfying activities after retirement from active radiology practice.

ABSTRACT

Sub-Events

Felicia Davis, Chicago, IL (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To provide updates from the Review Committee for Diagnostic Radiology. 2) To provide updates from ACGME. 3) To provide updates on ACGME's Next Accreditation System.

Sunday, Nov. 29 2:00PM - 3:30PM Location: S401AB

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credits: 1.50

Participants
Tony Nguyen, MLIS, Baltimore, MD, (tnguyen@hshsl.umd.edu) (Presenter) Nothing to Disclose
Holly Ann Burt, MLIS, Chicago, IL (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Understand how PubMed constructs a query and how to develop and refine effective search strategies in radiology. 2) Use PubMed tools including Clinical Queries, Related Articles, Single Citation Matcher and Loansome Doc. 3) Build focused searches using the Medical Subject Headings (MeSH) vocabulary for radiology and limit searches to radiology-oriented journals. 4) Understand how to save and download citations.

ABSTRACT

This hands-on workshop covers key searching techniques, changes to PubMed, and how to develop effective search strategies for PubMed and MEDLINE. Topics covered include: why keywords don't always give the results you expect, how to limit to specific journals, quick searches to find evidence-based citations, how to access full-text articles, and downloading citations to reference manager programs. The National Library of Medicine (NLM) provides free web access to nearly 24 million citations for biomedical and clinical medical articles through PubMed (available online at PubMed.gov). MEDLINE is a subset of PubMed which includes links to sites providing full text articles and to other related databases and resources.

Pediatric MR: Normal or Not?

Sunday, Nov. 29 2:00PM - 3:30PM Location: N228

Participants
Geetika Khanna, MD, MS, Iowa City, IA (Moderator) Nothing to Disclose

LEARNING OBJECTIVES
1) Differentiate normal and abnormal signal intensity patterns of abdominal structures in children. 2) Recognize normal developmental variants that can simulate abdominal pathology.

ABSTRACT

Sub-Events

RC124A Musculoskeletal MR

Participants
Nancy A. Chauvin, MD, Philadelphia, PA, (chauvinn@email.chop.edu) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Describe the MR appearance of normal marrow conversion in the developing skeleton. 2) Identify common pediatric marrow pitfalls that might be mistaken for pathology. 3) Describe the MR appearance of common bone marrow abnormalities in children.

ABSTRACT

RC124B Brain and Spine

Participants
Tina Y. Poussaint, MD, Boston, MA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Assess MR features associated with normal brain and spine development and maturation. 2) Identify abnormal MR imaging features associated with specific brain diseases and disorders of development in childhood.

ABSTRACT

In pediatric neuroradiology, magnetic resonance imaging is used to assess central nervous system (CNS) disease in the infant, child, and teenager. This requires 1) an understanding of normal brain development and maturation from gestation through adolescence; 2) a technical mastery of the neuroimaging techniques that are used in evaluating brain diseases of childhood; and 3) an overall grasp of the imaging features of numerous brain pathologies, both acquired and congenital. This lecture will focus on the common MR imaging features of the normal pediatric brain and spine and will compare and contrast with MR imaging features in specific brain diseases and disorders of development.

RC124C Abdominal MR

Participants
Geetika Khanna, MD, MS, Iowa City, IA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Differentiate normal and abnormal signal intensity patterns of abdominal structures in children. 2) Recognize normal developmental variants that can simulate abdominal pathology.
Identifying and Distinguishing Treatment Complications on FDG PET/CT

LEARNING OBJECTIVES

1) Identify iatrogenic causes of FDG-avidity on FDG PET/CT and distinguish them from FDG-avid malignancy. Iatrogenic causes of FDG-avidity include changes caused by surgery (inflammation at sites of incision, pleurodesis inflammation, transposition of ovaries/testes), radiation (pneumonitis, esophagitis, hepatitis), and drugs (bleomycin pneumonitis, bisphosphonate osteonecrosis, ipilimumab enterocolitis). Familiarity with usual and unusual causes of iatrogenic FDG-avidity will improve accuracy of FDG PET/CT reporting.

ABSTRACT

Fluorine 18 fluorodeoxyglucose (FDG) positron emission tomography / computed tomography (PET/CT) is increasingly used in the initial staging, evaluation of treatment response and surveillance of many malignancies. Uptake of FDG is substantially increased in most malignancies compared with its uptake in normal tissues, and FDG-avidity often leads to cancer detection earlier than abnormalities on anatomic imaging. However, FDG is not a cancer-specific agent, and FDG-avidity can be seen in many benign processes. It can be particularly challenging to discriminate malignancy from benign FDG-avid changes caused by surgery and procedures, radiation, and chemotherapy. FDG-avid lesions caused by surgery and procedures includes inflammation at sites of incision or dissection, inflammation from vascular compromise or surgical retraction, surgical transposition of structures with physiologic FDG-avidity (such as ovaries or testes), and pleurodesis inflammation. Radiation may induce FDG-avid pneumonitis, esophagitis, or hepatitis, as well as osteoradionecrosis or fractures. FDG-avid chemotherapy complications include pneumonitis, osteonecrosis, enterocolitis, and pancreatitis. Granulocyte Colony Stimulating Factor for treatment of bone marrow suppression after chemotherapy induces temporary increases of FDG-avidity in the bone marrow and spleen. In this review we illustrate common and unusual iatrogenic causes of FDG-avidity that can confound FDG PET/CT interpretation. Familiarity with these cases will improve accuracy of FDG PET/CT interpretation.

Imaging Musculoskeletal Complications

LEARNING OBJECTIVES

1) To recognize the osseous and soft tissue complications of tumor treatment, specifically those caused by radiation, chemotherapy, and surgery. These include radiation osteitis, osteonecrosis, insufficiency fractures, secondary malignancy, myositis and myonecrosis, and muscle denervation changes.

ABSTRACT

Musculoskeletal complications of tumor treatment are relatively common, often symptomatic, and therefore, an important cause of morbidity in the posttreatment cancer patient. Radiation causes local marrow changes such as osteitis, osteonecrosis and osteopenia, predisposing to insufficiency fractures. It may also cause local muscle damage, most commonly myositis, but occasionally myonecrosis. A rare but especially dreaded complication of radiation is secondary bone or soft tissue sarcoma, which will also be described. Chemotherapy, particularly protocols that include high doses of steroids, predisposes to osteonecrosis. And finally, surgical resection of extremity tumors, either primary or metastatic, may lead to muscle denervation changes. The bones and soft tissues should be carefully reviewed on all surveillance imaging, be it radiographs, CT or MRI, to exclude the presence of these often treatable complications.

GI Complications

LEARNING OBJECTIVES
1) To recognize the complications caused by chemotherapy and radiation specifically those that occur in the GI tract including the liver and the pancreas. These include perforations, abscess formation, radiation enteritis, insufficiency fractures and secondary malignancy.

**ABSTRACT**

Several complications can occur in the GI tract following surgery. Similarly chemotherapy can cause a myriad of complications such as perforation, abscesses and enteritis. Radiation therapy can result in radiation enteritis and occurrence of radiation induced cancer.

**Honored Educators**

Presenters or authors on this event have been recognized as RSNA Honored Educators for participating in multiple qualifying educational activities. Honored Educators are invested in furthering the profession of radiology by delivering high-quality educational content in their field of study. Priya R. Bhosale, MD - 2012 Honored Educator

**RC118D Pulmonary Complications**

Participants
Michelle S. Ginsberg, MD, New York, NY (Presenter) Nothing to Disclose

**LEARNING OBJECTIVES**

1) To recognize complications in the postoperative thoracic patient in both immediate and late periods. In the immediate period this will include lobar collapse, hemorrhage, pulmonary edema, pneumonia, as well as rarer complications such as bronchopleural fistula, chylothorax and lung torsion. In the later period it is important to follow these patients and to recognize and distinguishing recurrent tumor from treatment changes and new primary tumors.

**ABSTRACT**
Read with the Experts (Cardiac Radiology) (An Interactive Session)

Sunday, Nov. 29 2:00PM - 3:30PM Location: N226

Participants
Frank J. Rybicki III, MD, PhD, Ottawa, ON (Moderator) Research Grant, Toshiba Corporation;
Frank J. Rybicki III, MD, PhD, Ottawa, ON (Presenter) Research Grant, Toshiba Corporation;
Satinder P. Singh, MD, Birmingham, AL, (ssingh@uabmc.edu) (Presenter) Nothing to Disclose
Sanjeev Bhalla, MD, Saint Louis, MO (Presenter) Nothing to Disclose
Jacobo Kirsch, MD, Weston, FL (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) To illustrate common cardiac pathologies encountered in noninvasive imaging. 2) To review imaging protocols designed to best depict cardiac pathology. 3) To review image post-processing tools to render cardiac imaging findings for interpretation and communication with referring clinicians. Please bring your charged mobile wireless device (phone, tablet or laptop) to participate.

ABSTRACT
This session will include live reads with experts in cardiac radiology to meet the learning objectives. Specific cases and clinical scenarios will be presented to best demonstrate the pathology and the strategies for imaging and image interpretation.

Renal Cell Carcinoma: How Imaging Can Be Used to Select among Treatment Options and Monitor Response

Sunday, Nov. 29 2:00PM - 3:30PM Location: N227

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credits: 1.50

Participants
Erick M. Remer, MD, Cleveland, OH, (remere1@ccf.org) (Coordinator) Nothing to Disclose
Steven S. Raman, MD, Santa Monica, CA (Presenter) Nothing to Disclose
Raghunandan Vikram, MBBS, FRCR, Houston, TX (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) The attendee will learn how imaging can be used to predict renal tumor subtype and grade. 2) Imaging findings that guide renal tumor management toward percutaneous tumor ablation, partial, and radical nephrectomy will be described. 3) The use of imaging to evaluate patients after tumor ablation and nephrectomy will be reviewed. Assessment methods will be compared and complications will be illustrated. 4) Methods for assessing tumor response after chemotherapy such as RECIST, WHO, Choi / Modified Choi, SACT, and MASS criteria will be discussed with illustrative examples. Imaging appearances of post therapy complications will be reviewed.

Sub-Events

RC123A Developing Molecular Imaging Agents

Participants
Julie L. Sutcliffe, PhD, Sacramento, CA, (jlsutcliffe@ucdavis.edu) (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Describe the ideal properties of a molecular imaging agent. 2) Describe the in vitro validation of the molecular imaging agent. 3) Describe specific examples of successful molecular imaging agents.

RC123B Instrumentation (PET and CT) and Image Reconstruction

Participants
John Sunderland, PhD, Iowa City, IA, (john-sunderland@uiowa.edu) (Presenter) Research Grant, Siemens AG

LEARNING OBJECTIVES

1) Identify the primary design components of a modern PET/CT system. 2) Design and implement a PET/CT quality control program to assure high quality and quantitatively accurate clinical imaging. 3) Describe commonly used PET reconstruction algorithms and the practical impact of reconstruction parameters upon image quality and quantitation.

ABSTRACT

RC123C Basic Clinical Applications

Participants
Hubert J. Vesselle, MD, PhD, Seattle, WA (Presenter) Consultant, MIM Software Inc

ABSTRACT
Imaging of Pulmonary Fibrosis

Participants
David A. Lynch, MBCh, Denver, CO (Moderator) Research support, Siemens AG; Scientific Advisor, PAREXEL International Corporation; Consultant, Boehringer Ingelheim GmbH; Consultant, Gilead Sciences, Inc; Consultant, F. Hoffmann-La Roche Ltd; Consultant, Veracyte, Inc;

LEARNING OBJECTIVES
1) Understand the current clinical approach to diagnosis and management of pulmonary fibrosis. 2) Identify the major CT imaging features of the idiopathic interstitial pneumonias based on the revised ATS/ERS diagnostic criteria for IPF. 3) Differentiate idiopathic pulmonary fibrosis from nonspecific interstitial pneumonia and chronic hypersensitivity pneumonitis. 4) Identify important complications of IPF. 5) Understand evolving role of quantitative CT in assessment of lung fibrosis.

ABSTRACT
Recent clinical trials in idiopathic pulmonary fibrosis (IPF) have resulted in approval of two new treatments for this condition. Given the central role of the radiologist in making the CT diagnosis of IPF, it is critical to understand the diagnostic criteria for this condition as recently revised by the ATS/ERS, and to distinguish it from other fibrosing interstitial pneumonias including nonspecific interstitial pneumonia (NSIP), connective tissue disease related lung fibrosis (CVD-ILD), and chronic hypersensitivity pneumonitis (HP). The radiologist also has an important role in identifying complications of lung fibrosis including acute exacerbations and lung cancer. Substantial advances have been made in developing CT techniques for quantification of lung fibrosis, which correlate with clinical severity and with mortality.

Should I Scan That Patient? A Very Interactive Session on MR Safety and Regulations (An Interactive Session)

Sunday, Nov. 29 2:00PM - 3:30PM Location: E353C

AMA PRA Category 1 Credits ™: 1.50
ARRT Category A+ Credits: 1.50

Participants
Jeffrey C. Weinreb, MD, New Haven, CT (Presenter) Nothing to Disclose
Emanuel Kanal, MD, Pittsburgh, PA (Presenter) Consultant, Boston Scientific Corporation; Consultant, Medtronic, Inc; Consultant, St. Jude Medical, Inc; Consultant, Bayer AG; Investigator, Bracco Group; Royalties, Guerbet SA;

LEARNING OBJECTIVES
1) Analyze the cause and avoidance of a spectrum of common MR safety issues, including burns. 2) List the factors (including regulation and guidelines) which should be evaluated in order to determine the safety of MRI in patients with implants, devices, or foreign objects. 3) Answer questions from the audience concerning MRI safety issues

ABSTRACT
The major potential safety considerations in magnetic resonance imaging relate to those stemming from the static magnetic field, the time varying radiofrequency oscillating magnetic fields, the time varying switched gradient magnetic fields, the contrast agents often utilized in the MR imaging process, sedation/anesthesia and monitoring-related issues unique to the MR imaging environment, and cryogen related potential safety concerns. These can present confounding situations for MR practitioners faced with questions relating to the safety of exposing particular patients and devices, implants, or foreign bodies to MR imaging examinations. This session will introduce and briefly explain the above safety considerations, and highlight specific issues likely to confront MR practitioners in their daily practice by utilizing real-life examples. The methodology and reasoning process used to approach these clinical examples in determining risk-benefit ratios for accepting or rejecting such patients from MR exposure will be stressed. The emphasis will be on not so much the particular examples used, but rather having the attendee feeling more comfortable with the approach to such clinical and research situations in order to better enable them to appropriately address such questions in their own daily practice routines. Audience polling and interaction will be actively utilized throughout this session. This will help enable the attendee to not only hear the opinions of the presenters on the cases being discussed, but also to assess their own responses to the questions being posed relative to that of the other attendees of this session.
MRI: Imaging for Treatment Planning

Sunday, Nov. 29 2:00PM - 3:30PM Location: E353A

Participants
Eric Paulson, Milwaukee, WI (Moderator) Nothing to Disclose

ABSTRACT

1) Understand the advantages of MRI simulation for anatomical delineation in both external beam radiation therapy and brachytherapy. 2) Understand the differences between images obtained during MRI simulation versus diagnostic MRI. 3) Understand the current solutions to address technical challenges of using MRI for anatomical delineation in Radiation Oncology.

LEARNING OBJECTIVES

1) Get an overview of the most relevant functional MRI modalities are available. 2) Understand how they can be used to improve target definition. 3) Understand their limitations and specific concerns for use in radiation oncology.

ABSTRACT

In addition to anatomical imaging, MRI affords a range of functional techniques. Diffusion-weighted MRI images the restriction of water mobility in tissue, thus probing microanatomy. This is used to identify tumors and monitor response to treatment. Dynamic contrast-enhanced MRI shows the tracer kinetics of contrast agents and reflects the characteristics of the microvasculature, such as flow and permeability. These and other techniques can be used to improve target definition, and to characterize tumor tissue for radiotherapy dose painting.
**Participants**

**Sub-Events**

**RC110A  Uterus and Endometrium**

Participants  
Ruth B. Goldstein, MD, San Francisco, CA (*Presenter*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Be able to state the acceptable standards for endometrial assessment in women with abnormal vaginal bleeding. 2) Be able to recognize a uterine abnormality in a postmenopausal woman that warrants further evaluation including tissue sampling or MRI. 3) Be able to recognize and diagnose adenomyosis.

**RC110B  Ovarian Masses**

Participants  
Phyllis Glanc, MD, Toronto, ON (*Presenter*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Evaluate critical ultrasound features of adnexal masses that permit stratification into benign, indeterminate or suspicious for malignancy. 2) Incorporate the role of guidelines, consensus statements, risk prediction algorithms and serum biomarkers. 3) Consider the role of alternate imaging modalities such as MRI, CT, PET-CT. 4) Utilize appropriate management strategies.

**ABSTRACT**

There remains a gap between the state of the knowledge and translation into practice for the diagnosis and management of adnexal masses. Pelvic ultrasound remains the primary imaging modality in the greater majority of cases. Most ovarian masses can be correctly classified on the basis of their ultrasound characteristics, nonetheless many masses that are ‘almost certainly benign’ or even ‘indeterminate’ come to prompt surgical exploration, which is not always appropriate or without its potential risks. This session will explore further these characteristic findings but also will evaluate the role of serial ultrasound, additional modalities such as MR or CT, serum biomarkers, strategies such as IOTA simple rules and optimization of referral patterns.

**RC110C  Endometriosis**

Participants  
Luciana P. Chamie, MD, PhD, Sao Paulo, Brazil (*Presenter*) Nothing to Disclose

**LEARNING OBJECTIVES**

1) Define clinical and epidemiological aspects of endometriosis. 2) Define the importance of imaging mapping for endometriosis before clinical counseling. 3) Apply the most appropriate technique to investigate endometriosis. 4) Define the bowel preparation required for the transvaginal ultrasound to investigate endometriosis. 5) Apply the imaging algorithm to map deeply infiltrative endometriosis. 6) Assess the ultrasonographic findings of deeply infiltrative endometriosis in the most common sites such as bladder, vesicouterine pouch, retrocervical space, vagina, ureters, appendix and rectosigmoid colon. 7) Assess the ultrasonographic findings of ovarian endometriomas and differentiate them from functional cysts.

**ABSTRACT**

Endometriosis is a very common gynecological disease affecting millions of women in their reproductive life, often causing pelvic pain and infertility. Clinical history and physical examination may suggest endometriosis, but imaging mapping is necessary to identify the disease and mandatory for clinical counseling and surgical planning. Transvaginal ultrasound after bowel preparation is the best imaging modality as the first-line technique to evaluate patients suspected of endometriosis. The bowel preparation is relatively simple and include the day before and the day of the examination. This method is highly accurate to identify intestinal endometriosis and to determine which layers of the bowel wall are affected. In addition, it provides better assessment of small peritoneal lesions of the retrocervical space, vagina and bladder. Pelvic adhesions can also be evaluated during the exam.
LEARNING OBJECTIVES

1) Understand the history and development of nuclear imaging. 2) Become introduced to the advances of hybrid imaging. 3) Understand the impact of equipment development on medical physics support.

ABSTRACT

Nuclear imaging has not received the attention or development enjoyed by other imaging modalities. Nevertheless, our understanding of nuclear imaging and development of protocols and hybrid systems has led to new requirements for testing and other medical physics support. This presentation will discuss these developments and the impact they have had on the medical physics support needed by nuclear imaging departments.

LEARNING OBJECTIVES

1) Learn acceptance testing and commissioning of gamma cameras/SPECT / and PET-CT systems. 2) Describe routine quality control procedures and their frequencies. 3) Become familiar with ACR accreditation of planar, SPECT, and PET systems. 4) Learn about various potential image artifacts of gamma camera, SPECT and PET systems.

ABSTRACT

The aim of this lecture is to provide the audience with an overview of the current medical physics testing procedures that are performed on gamma cameras, SPECT and PET systems. The lecture will be divided into 3 main parts; the first part will describe the tests performed for acceptance testing of these systems while the second part will describe the routine quality control and assurance tests and their frequencies. The last part of the lecture will focus on the ACR accreditation process and the necessary phantom imaging for gamma cameras, SPECT and PET systems. Throughout the lecture, examples of potential image artifacts will be presented.

LEARNING OBJECTIVES

1) Become familiar with new physics metric and analytics in nuclear imaging. 2) Determine testing implication of emerging technologies in nuclear imaging. 3) Envision the clinical implementation of new physics metrics and analytics.

ABSTRACT

Although the basic science of nuclear imaging has remained relatively unchanged since its inception, advances in instrumentation continue to advance the field into new territories. With a great number of these advances occurring over the past decade, the role and testing strategies of clinical nuclear medicine physicists must evolve in parallel. This presentation is designed to highlight some of the recent advances from a clinical medical physicist perspective and provide ideas and motivation for designing better evaluation strategies. Topics include improvement of traditional physics metrics and analytics, testing implications of hybrid imaging and advanced detector technologies, and strategies for effective implementation into the clinic.

Sub-Events

RC109A Liver Specific Contrast Agents

Participants
Giuseppe Brancatelli, MD, Palermo, Italy, (gbranca@yahoo.com) (Presenter) Speaker, Bayer AG

LEARNING OBJECTIVES
1) Describe the mechanism of action of liver specific contrast agents. 2) Understand the added value of liver-specific contrast agents in the characterization of focal liver lesions. 3) Identify the most common pitfalls and limitations of liver specific contrast agents.

ABSTRACT

RC109B Diffusion-weighted Imaging

Participants
Ihab R. Kamel, MD, PhD, Baltimore, MD (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Discuss the basic concepts for DWI in body applications. 2) Describe the emerging role of DWI in assessing response in cancer. 3) Discuss the application of DWI in whole body imaging.

RC109C MR Perfusion

Participants
Hersh Chandarana, MD, New York, NY (Presenter) Equipment support, Siemens AG; Software support, Siemens AG; Consultant, Bayer, AG;

LEARNING OBJECTIVES
1) Understand basic principles of Perfusion Weighted Imaging (PWI) 2) Understand steps involved in performing PWI 3) Clinical applications and limitations will be highlighted.

ABSTRACT

ABSTRACT:DCE-MRI refers to the high temporal resolution imaging performed before and after administration of gadolinium contrast. This dynamic contrast-enhanced (DCE)-MRI can be used to assess organ and/or tumor perfusion (PWI). PWI can provide insight into tumor vascularity and possibly early treatment response to antiangiogenic therapies. Basic concept of perfusion weighted imaging as well as acquisition and image analysis schemes will be briefly discussed. Potential clinical applications and challenges to clinical implementation will be highlighted.

RC109D PET MR

Participants
LEARNING OBJECTIVES

1) Understand the unique challenges in the physics underlying PET/MRI. 2) Understand the unique role of PET/MRI in diagnosing and staging GI Malignancies. 3) Understand the potential future role of PET/MRI in both diagnosing GI malignancies and in assessing novel therapeutic response.

ABSTRACT
How to Avoid Failure: Qualities of a Successful Leader

Sunday, Nov. 29 2:00PM - 3:30PM Location: E350

LEARNING OBJECTIVES

1) Develop an understanding of the essential traits and skills required for a leader to be successful, i.e., traits and states. 2) Develop an understanding of the common errors made by leaders in academic and private practices enabling the attendee to obtain the lessons' without the 'lumps.' 3) Acquire the skills of succession planning needed to ensure that the success of your organization is sustainable over time and leadership transitions. (This course is part of the Leadership Track)

Sub-Events

RC132A How Leaders Succeed and Fail

Participants
James A. Brink, MD, Boston, MA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

RC132C Leadership

Participants
N. Reed Dunnick, MD, Ann Arbor, MI (Presenter) Nothing to Disclose

LEARNING OBJECTIVES

1) Recognize historical examples of leaders, in addition to how you can recognize and emulate their favorable characteristics that draw you to their leadership attributes. 2) Understand an overview of leadership references, where and how to access the same, how the related body of knowledge has evolved, and current perspectives concerning leaders and leadership. (This course is part of the Leadership Track)
**Anatomy and Pathology of the Pharynx and Larynx**

**Sunday, Nov. 29 2:00PM - 3:30PM Location: E450A**

**Participants**

**Sub-Events**

**RC106A  Imaging the Nasopharynx**

Participants
Nancy J. Fischbein, MD, Stanford, CA, (fischbein@stanford.edu) *(Presenter)* Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the normal anatomy of the nasopharynx. 2) Illustrate the appearance and patterns of spread of nasopharyngeal carcinoma. 3) Describe additional pathologies of the nasopharynx, along with imaging pearls and pitfalls.

**ABSTRACT**

The nasopharynx is the uppermost portion of the upper aerodigestive tract, and it is located posterior to the nasal cavity, inferior to the sphenoid sinus, and anterior to the clivus and craniovertebral junction, above the level of the soft palate. Given its intimate relationship with the central skull base, detailed knowledge of the anatomy of the central skull base, including its canals and foramina, is critical to understanding the spread of disease in this region. Though CT is helpful in imaging diseases of this region, a good knowledge of MR anatomy, and an understanding of optimal MR imaging protocols, is essential to proper imaging and imaging interpretation of diseases of the nasopharynx. We will spend some of our time discussing nasopharyngeal carcinoma, including its demographics, staging, and imaging appearance, but we will also review benign pathologies of the nasopharynx, and other malignant entities. We will also review some imaging pearls for each entity, and also imaging pitfalls, as there are many ways in which the unwary radiologist can overlook or misinterpret significant pathology in the nasopharynx.

**RC106B  Imaging the Oropharynx**

Participants
Suresh K. Mukherji, MD, Northville, MI *(Presenter)* Nothing to Disclose

**LEARNING OBJECTIVES**

1) Review the normal anatomy of the oropharynx. 2) Illustrate the normal spread patterns of tumors involving various subsites of the oropharynx. 3) Describe the appearance of various infectious and inflammatory processes involving the oropharynx.

**ABSTRACT**

Imaging plays a crucial role in evaluating the oropharynx. This talk will review the normal anatomy and malignancies involving the oropharynx. The presentation will also review various inflammatory and infectious processes that involve different parts of the oropharynx.

**RC106C  Imaging the Larynx and Hypopharynx**

Participants
Peter M. Som, MD, New York, NY *(Presenter)* Nothing to Disclose

**LEARNING OBJECTIVES**

1) The registrants will learn the intimate relationship between the larynx and hypopharynx. 2) The anatomy of the larynx and hypopharynx will be reviewed. 3) The major pathology of these structures will be reviewed.

**ABSTRACT**

The larynx is situated within the hypopharynx and thus their intimate relationship. The anatomy of the larynx and the hypopharynx will be reviewed, especially as it pertains to neoplasms. The scope of inflammatory and neoplastic diseases that affect these structures will be reviewed with particular attention to what should be included in the radiologist’s report to create a pertinent and meaningful report.
**Contemporary Problems in Arthritis Evaluation (An Interactive Session)**

Sunday, Nov. 29 2:00PM - 3:30PM Location: E450B

**MK**

AMA PRA Category 1 Credits™: 1.50
ARRT Category A+ Credits: 1.50

**Participants**

Donald J. Flemming, MD, Hershey, PA (Director) Royalties, Reed Elsevier

**LEARNING OBJECTIVES**

1) Describe the multimodality imaging features of common arthropathies. 2) Describe key imaging features that help distinguish one arthritis from another commonly confused entity. 3) Describe important clinical features that help establish the correct diagnosis of an arthropathy. Please bring your charged mobile wireless device (phone, tablet or laptop) to participate.

**ABSTRACT**

The purpose of this presentation is to discuss how to differentiate commonly confused arthropathies using a case based interactive format. The utility of multiple modalities and incorporation of clinical data in establishing a correct diagnosis will be reviewed.

**Sub-Events**

**RC104A Differentiating Rheumatoid Arthritis from Crystal Deposition Diseases**

**Participants**

Donald J. Flemming, MD, Hershey, PA (Presenter) Royalties, Reed Elsevier

**LEARNING OBJECTIVES**

1) Describe the imaging features that differentiate rheumatoid arthritis and gout. 2) Describe the imaging features that differentiate rheumatoid arthritis and calcium pyrophosphate deposition disease.

**ABSTRACT**

Radiologists can have a tremendous impact on care of a patient suffering from an arthritis by confirming or establishing the correct diagnosis. Prevention of joint damage hinged on the correct diagnosis and therapeutic regimen. The purpose of this presentation is to review the imaging features that assist in differentiating rheumatoid from crystal deposition disease (gout and calcium pyrophosphate and hydroxyapatite deposition disease). A case based format will be used to demonstrate the critical radiographic, MRI, CT and ultrasound features that help establish the correct diagnosis.

**RC104B Differentiating Appendicular Inflammatory from Degenerative Arthritis**

**Participants**

Thomas M. Link, MD, PhD, San Francisco, CA, (thomas.link@ucsf.edu) (Presenter) Research funded, General Electric Company; Research funded, Insitec Ltd; Royalties, Springer Science+Business Media Deutschland GmbH; Research Consultant, Pfizer Inc;

**LEARNING OBJECTIVES**

1) To classify imaging studies of patients with arthropathies as inflammatory or degenerative. 2) To differentiate specific radiographic criteria of inflammatory arthropathies from those of degenerative osteoarthritis of the appendicular skeleton. 3) To identify findings that are found in both inflammatory and degenerative arthropathies, in particular in erosive osteoarthritis.

**ABSTRACT**

In general appendicular inflammatory arthropathies are characterized by loss of bone with juxta-articular osteopenia and erosive changes while degenerative arthritis shows increased bone formation with subchondral sclerosis and osteophytes. However, there is overlap as inflammatory arthropathies will eventually develop secondary degenerative changes and there is an erosive form of osteoarthritis (OA), which is typically found in older women. There are a number of criteria to differentiate OA and inflammatory arthropathies. These include location of abnormalities in the appendicular skeleton, which greatly helps to differentiate rheumatoid arthritis from OA (metacarpophalangeal/metatarsophalangeal joints in rheumatoid arthritis versus distal and proximal interphalangeal joints in OA) but not psoriatic arthritis and OA (distal and proximal interphalangeal joints in OA). Also inflammatory arthropathies and OA are both found at the radiocarpal, intercarpal and carpo-metacarpal joint 1. Differentiating erosive OA and psoriatic arthritis is a particular challenge as they both are erosive and may be found in the same locations. This lecture will present typical and more problematic cases of inflammatory and degenerative arthropathies, identify typical and overlapping findings and provide the attendees with a diagnostic approach to these entities.

**RC104C Differentiating Sacroiliitis from Its Mimickers**

**Participants**

David C. Salonen, MD, Toronto, ON (Presenter) Consultant, AbbVie Inc; Consultant, Johnson & Johnson;

**LEARNING OBJECTIVES**

1) Discuss radiographic and MR criteria ‘necessary’ for the diagnosis of sacroiliitis. 2) Describe the imaging features that differentiate inflammatory sacroiliitis from its mimickers.

**ABSTRACT**
Differentiating Ankylosing Spondylitis from Spinal Degenerative Disease

Participants
Robert G. Lambert, MBBCh, Edmonton, AB (Presenter) Research Consultant, Abbott Laboratories

LEARNING OBJECTIVES
1) Differentiate specific patterns of bone marrow abnormality on spine MRI from non-specific changes. 2) Describe the patterns of bone formation on spine radiography in middle-aged patients that distinguish between degenerative causes and spondyloarthritis. 3) Recommend which patients with spinal ossification need further imaging to distinguish between spondyloarthritis and DISH.

ABSTRACT
Diffuse idiopathic skeletal hyperostosis (DISH) is a degenerative disorder characterized by flowing ossification in the spine occurring primarily in the anterior longitudinal ligament, and to a lesser extent, in paravertebral tissues and the peripheral part of the annulus fibrosus. The ossification is usually most prominent along the anterior and right anterolateral aspects of thoracic vertebral bodies and, on lateral x-ray, radiolucency may be noted between new bone and the vertebral body. Current classification criteria for DISH require spinal ankylosis across 3 consecutive intervertebral discs and less extensive ankylosis may present a diagnostic challenge when criteria are not met. Concomitant disc degeneration is frequent but is less prevalent at fused levels. DISH may involve the sacroiliac (SI) joints but with relative preservation of articular cartilage. Spondyloarthritis (SpA) is a group of inflammatory disorders that involve the joints and entheses of the axial and peripheral skeleton and is typified by ankylosing spondylitis (AS). Spinal involvement is characterized by inflammation at the attachment of the annulus fibrosus. Osteitis may be seen in the form of erosion and/or sclerosis of the vertebral corer and "squaring" of the vertebral bodies on lateral views of the spine is caused by adjacent periosteal reaction. In the periphery of the annulus fibrosus, formation of syndesmophytes are seen as vertical bony spurring that may extend to bridge the disc causing ankylosis. The inflammatory process may result in ankylosis of the costotransverse, costovertebral, and facet joints and interspinous ligaments. These two conditions are easily distinguished when seen in their common presentation. However, patients with an older than usual onset of SpA over the age of 40 may be hard to distinguish from early DISH and disc degeneration is common at all ages regardless of both DISH and SpA. In many cases when the diagnosis is uncertain, further imaging, especially with MRI, may be useful to distinguish between these two entities. However while some patterns of MRI involvement are highly specific for one condition or another, often bone marrow abnormalities in the spine are non-specific and being able to distinguish between these patterns is of considerable diagnostic importance.

Monitoring Response to Disease Modifying Therapy

Participants
Eric Y. Chang, MD, San Diego, CA (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Describe the role of the radiologist in the management of arthropathies. 2) Compare the ability of different imaging modalities to detect inflammation and structural alteration. 3) Assess the response after disease modifying therapy according to established criteria.

ABSTRACT
Sunday Afternoon Plenary Session  
Sunday, Nov. 29 4:00PM - 5:45PM  Location: Arie Crown Theater

**PS12A  Report of the RSNA Research and Education Foundation**  
Participants  
Burton P. Drayer, MD, New York, NY (Presenter) Advisor, Hologic, Inc  

Abstract  
The RandE Foundation - Our Future is Now  
This year marks the 100th anniversary of the RSNA's founding. As radiology looks toward the future, one wonders what the next 100 years will look like for our specialty and whether the central role of radiologists in healthcare will be sustained. Analogous to our clinical radiology mantra, if we are not at the radiology research table we will be on the menu. As a leading global force in radiology, the RSNA is poised to lead the specialty into the next century and exceed the incredible success of the past 100 years. The RandE Foundation will play a key role in radiology's future by continuing its support of inspiring investigators and those pursuing innovative approaches to education. To meet these research and education needs head-on, the Foundation launched Inspire-Innovate-Invest, The Campaign for Funding Radiology's Future® at last year's annual meeting. This bold campaign seeks to raise $17.5 million to fund grants in radiologic research and education, bridging the gaps in funding for promising investigators and educators. To date our campaign has been a success with individuals, private practice and corporate donors generously pushing us to the mid-way point in our goal. There is still a long way to go. The future of our specialty depends on the commitment and generosity of each of us, the members of the imaging community. This year, the Foundation will fund 92 grants totaling $3.6 million. The RandE is funding 25% of our ever increasing number of excellent grant applications. While pleased with these achievements, imagine what the RandE Foundation could fund with additional support from all of us as radiology colleagues? During the meeting week, please take time to visit the RandE Foundation Booth, located on Level 3 of Lakeside Center to learn more about how you can be a part of the campaign and support the RandE Foundation and the future robustness of our specialty.

Jorge A. Soto, MD - 2014 Honored Educator  
Jorge A. Soto, MD - 2015 Honored Educator  
Jonathan B. Kruskal, MD, PhD - 2012 Honored Educator
LEARNING OBJECTIVES
1) Learn the Standard Tessellation Language (STL) file format that is used in 3D printing. 2) Be exposed to a software package to enable segmentation of DICOM images using semi-automated and manual segmentation algorithms, allowing the user to demarcate desired parts. The most commonly used tools are thresholding, region growing, and manual sculpting. 3) Learn refinement of an output STL output so that it can be optimized for accurate printing of the desired anatomy and pathology. This step uses Computer Aided Design (CAD) software is used to perform steps such as "wrapping" and "smoothing" to make the model more homogeneous.

ABSTRACT
"3D printing" refers to fabrication of a tangible object from a digital file by a 3D printer. Materials are deposited layer-by-layer and then fused to form the final object. There are several 3D printing technologies that share similarities but differ in speed, cost, and resolution of the product. Digital Imaging and Communications in Medicine (DICOM) image files cannot be used directly for 3D printing; further steps are necessary to make them readable by 3D printers. The purpose of this hands-on course is to convert a set of DICOM files into a 3D printed model through a series of simple steps. Some of the initial post-processing steps may be familiar to the radiologist, as they share common features with 3D visualization tools that are used for image post-processing tasks such as 3D volume rendering. However, some are relatively or completely new to radiologists, including the manipulation of files in Standard Tessellation Language (STL). It is the STL format that is read by the 3D printer and used to output the hand held part of the patient’s anatomy. This 90 minute session will begin with a DICOM file and will proceed through the steps to create a printable STL file. An extensive training manual will be provided before the meeting. It is highly recommended that participants review the training manual to optimize the experience at the workstation.

Participants
William J. Weadock, MD, Ann Arbor, MI (Presenter) Owner, Weadock Software, LLC
Sarah C. Abate, BS, Ann Arbor, MI (Presenter) Nothing to Disclose

LEARNING OBJECTIVES
1) Review the components of an optimal slide presentation. 2) Learn about common errors made in slide preparation and how they can be avoided. 3) Learn about how to improve the quality of a presentation by using optimal different slide backgrounds, font size and color, and image sizes. 4) Learn tips to ensure a smooth presentation.

ABSTRACT
Electronic presentations are very common in radiology practice. This hands-on demonstration and questions and answer session will show attendees how to optimize their presentations. The focus will be on the use of slide templates, color selection (font and background), font and image size, and animations. Additional review of image and video display and management will be covered. Demonstrations will include tips to decrease time creating and modifying presentations. Bring your questions!
